Table of Contents

Section A: An Overview of Water Quality in Ohio	A-1
Section B: Ohio's Water Resources	
B1: Facts and Figures	B-1
B2: 2020 Water Quality Goals	B-9
Section C: Managing Water Quality	
C1: Program Summary – Surface Water	C-1
C2: Program Summary – Environmental and Financial Assistance	C-20
C3: Program Summary – Drinking and Ground Waters	C-20
C4: Program Summary – Environmental Services	C-21
C5: Cooperation among State Agencies and Departments	
C6: Funding Sources for Pollution Controls	C-23
C7: Harmful Algal Blooms Responses and Assessments	C-28
C8: New 303(d) Vision Implementation in Ohio	C-35
Section D: Framework for Reporting and Evaluation	
D1: Assessment Units	D-2
D2: Evaluation of the Ohio River	D-5
D3: Evaluation of Lake Erie	D-5
D4: Ohio's Water Quality Standards and Use Designations	D-6
D5: Sources of Existing and Readily Available Data	D-9
D6: Public Involvement in Compiling Ohio's Section 303(d) List of Impaired Waters	D-12
(June 2, 2015)	D-14
D6.1.1: Web Page with Instructions for Submitting Level 3 Credible Data	
D6.2: Web Page Announcing 2016 Integrated Report Preparation	
D6.3: Notice of Availability and Request for Comments CWA Section 303(d) TMDL	
Priority List for 2016	D-23
Section E: Evaluating Beneficial Use: Human Health (Fish Contaminants)	
E1: Background	E-1
E2: Rationale and Evaluation Method	E-1
E3: Results	E-7
E4: Supplemental Information	E-33
E4.1: Calculation of Fish Concentrations from Water Quality Standards Inputs	E-33
E4.2: What's the Difference between the Fish Consumption Advisory Decision and	
the Impairment Decision?	E-37
Section F: Evaluating Beneficial Use: Recreation	
F1: Background	
F2: Evaluation Method	F-2
F3: Results	
F3.1: Lake Erie Public Beaches	
F3.2: Rivers and Streams	
F3.3: Inland Lakes	F-20

Section G: Evaluating Beneficial Use: Aquatic Life	
G1: Background and Rationale	G-1
G1.1: Background	
G1.2: General Determination of Attainment Status	G-2
G2: Evaluation Method	
G2.1: Rivers and Streams: Large River Assessment Units (LRAUs)	
G2.2: Rivers and Streams: Watershed Assessment Units (WAUs)	
G2.3: Lake Erie Shoreline and Islands: Lake Erie Assessment Units (LEAUs)	
G3: Results	G-7
G3.1: LRAUs	
G3.2: WAUs	
G3.3: LEAUs	G-10
Section H: Evaluating Beneficial Use: Public Drinking Water Supply	
H1: Background	
H2: Evaluation Method	
H2.1 Beneficial Use Designation	
H2.2 Water Quality Standards	
H2.3 Attainment Determination	
H2.4 Data Sources and Requirements	
H2.5 Ohio River Assessments	
H3: Results	_
H4: Supplemental Information	H-17
Section I: Considerations for Future Lists	
I1: Wetlands	
I1.1 Middle Scioto TMDL	
I1.2 Status of Ohio's Wetland Resources	
I1.3 Next Steps	
I2: Mercury Reduction at Ohio EPA	
I2.1: Ohio Law

Executive Summary

The *Ohio 2016 Integrated Water Quality Monitoring and Assessment Report* summarizes water quality conditions in the State of Ohio. The report satisfies Ohio's water quality reporting requirements under Sections 303(d), 305(b) and 314 of the Clean Water Act. The report was last updated in 2014. **Analysis and listing changes are based on data collected during 2013 and 2014 for all uses**; recreation and public drinking water supplies uses also included data from 2015, therefore impairment listings may not reflect current conditions.

Using methods devised to determine the suitability of waters for four specific uses—aquatic life (fish and aquatic insects), recreation (such as boating and swimming), human health (related to fish tissue contamination) and public drinking water supplies—available data were compared with water quality goals. The results indicate which waters are meeting goals and which are not. Waters not meeting the goals for one or more of the four types of uses are referred to as *impaired*. The waters found to be impaired are prioritized and scheduled for further study and restoration.

The report describes the methods used to judge impairment of each type of use and have evolved in each reporting cycle as the Agency gains access to more data and develops better ways to interpret them.

Results are reported for 1,538 watershed units, 38 large river units (in Ohio's 23 rivers that drain more than 500 square miles) and three Lake Erie shoreline units (including waters within 500 yards of public drinking water intakes). Additional information on streams draining between 20 and 500 square miles is presented as this subset of waterbodies is used to calculate and track progress of Ohio's 80 percent full attainment by 2020 goal for wading and principal streams and rivers.

Ohio's large rivers reflected a small decline in percent of monitored miles in full attainment compared to the same statistic reported in the 2014 IR. The "100% full attainment by 2020" aquatic life goal statistic for Ohio's largest rivers now stands at 87.4 percent, down 1.8 percent from the 2014 report. Conversely, smaller streams continue to improve with the average watershed score increasing from 64.2 percent to 66.1 percent of monitored sites in full aquatic life use attainment. The top reasons for aquatic life impairment continue to be sediment, nutrients, habitat modification, hydromodification and organic enrichment.

For the human health use (fish tissue), PCB contamination in fish is the cause of most of the human health impairments in Ohio. Mercury is the second leading cause.

The chemicals of concern causing impairment of the public drinking water supply use include nitrate, atrazine and cyanotoxin (due to certain algae). The primary source of the chemicals is nonpoint source runoff from agricultural land use. Additional sources of nitrate include home and commercial fertilizer application, failing septic systems, unsewered areas and wastewater treatment plant discharges. Of the 123 public drinking water supply assessment units, 19 are now listed as impaired by algae, with another 19 on the watch list for algae (more than double the 2014 report).

The recreation use analysis focuses on the number of bacteria in the water. For Lake Erie public beaches, the frequency of swimming advisories varies widely, ranging from 1.3 percent to over 60

percent. Generally, beaches located near population centers have the most problems. Results are also reported for streams and inland lakes.

Of the 6,316 possible category assignments, the 2016 303(d) list includes changes in 463, with 132 delistings and 331 new listings. Most 303(d) removals and new listings are due to new data.

Changes since the 2014 Integrated Report

Changes made between the 2014 Integrated Report and the 2016 Integrated Report are as follows:

- The Harmful Algal Bloom (HAB) information has been moved from Section I to Section C7.
- The report contains a new section dedicated to Ohio's 303(d)/TMDL Program Vision (Section C8).
- Information was added to the end of Section H regarding an error that was discovered in the 2014 list pertaining to improperly listed PDWS use waters.
- A description of "Near Term Priorities for Ohio EPA" has been added to Section J2.
- The report contains a new subsection discussing Ohio's approach to addressing nutrients in Lake Erie (Section J3), and Lake Erie information has been added or moved to Sections C1 and D3.
- Section L5 (Monitoring and TMDL Schedules for Ohio's Watershed and Large River Assessment Units) was removed from the report; consequently, previous Section "L6" was renumbered/labeled.

An Overview of Water Quality in Ohio

Clean water is important to Ohio's economy and standard of living.

Ohio is an economically important and diverse state with strong agriculture, manufacturing and service industries. Ohio is also a water-rich state bounded by Lake Erie on the north and the Ohio River on the south, with more than 25,000 miles of named and designated streams and rivers within its borders. The suitability of these waters to support society's needs for water supplies and recreation is critical to sustaining Ohio's economy and the standard of living of Ohio citizens. Surface waters such as rivers, streams and lakes provide the majority of water used for public drinking water; for recreation such as swimming, boating, and fishing; and for industrial uses including manufacturing, power generation, irrigation and mining.

Ohio EPA monitors water quality in Ohio and reports its findings.

Monitoring the quality of Ohio's valuable water resources is an important function of the Ohio Environmental Protection Agency (Ohio EPA). Since the early 1970s, Ohio EPA has measured the quality of Ohio's water resources and worked with industries, local governments and citizens to restore the quality of substandard waters. This particular report, updated every two years, is required by the federal Clean Water Act to fulfill two purposes: 1) to provide a summary of the status of the State's surface waters; and 2) to develop a list of waters that do not meet established goals—the "impaired waters."

Under the Clean Water Act, once impaired waters are identified the state must take action to improve them. Typically, the actions include developing restoration plans [total maximum daily loads (TMDLs)], water quality based permits and nonpoint source pollution control measures. As such, this report is an important document that provides information and direction to much of the State's work in water quality planning, monitoring, financial/technical assistance, permitting and nonpoint source programs.

For nearly 40 years, Ohio EPA has developed innovative monitoring methods that directly measure progress toward the goals of the Clean Water Act. Generally recognized as a leader in water quality monitoring, Ohio uses the fish and aquatic insects that live in streams to assess the health of Ohio's flowing waters. Aquatic animals are generally the most sensitive indicators of pollution because they inhabit the water all of the time. A healthy stream community is also associated with high quality recreational opportunities (e.g., fishing and boating). Stream assessments are

based on the experience gained through the collection of over 26,000 fish population samples and nearly 13,500 aquatic insect community samples.

In addition to biological data, Ohio EPA collects information on the chemical quality of the water (nearly 210,000 water chemistry samples), sediment and wastewater discharges; data on the contaminants in fish flesh; and physical habitat information about streams. Taken together, this information identifies the factors that limit the health of aquatic life and that constitute threats to human health.

Results show water quality is impaired but continues to improve especially in the smaller watersheds.

Ohio EPA developed methods to determine how well Ohio's waters support four specific uses of water: 1) human health impacts related to fish tissue contamination; 2) recreation; 3) human health impacts related to drinking water; and 4) aquatic life (fish and aquatic insects). Available data were compared with established water quality goals and the results of the comparison indicate which waters are meeting goals and which are not. The results for each use are discussed in the next few pages.

To assess the **human health impacts related to fish tissue contamination**, Ohio EPA uses the same data that are used to generate Ohio's sport fish consumption advisory. Although the data are the same, the analyses are different. Ohio EPA urges Ohio's anglers to consult the sport fish consumption advisory regarding which and how much fish to eat. A link to the fish consumption advisory website is available at the end of this section.

For analysis in this report, approximately half of Ohio's watershed assessment units (WAUs) and one-third of publicly owned lakes have some fish tissue data available. Of those, about 9.5 percent of the WAUs and half of the lakes do not have enough data to determine the impairment status. About one-third of the monitored WAUs are "unimpaired" for the contaminants, while almost two-thirds of the WAUs are "impaired." For lakes, almost 6 percent are impaired while approximately 40 percent are not impaired by the six fish tissue contaminants [mercury, polychlorinated biphenyls (PCBs), chlordane,

mirex, hexachlorobenzene and dichlorodiphenyltrichloroethane (DDT)]. The most common contaminant is PCBs, followed by mercury. A few waters contain fish whose flesh is contaminated by dichlorodiphenyltrichloroethane (DDT), mirex or hexachlorobenzene; data show no streams or lakes with fish contaminated by lead. PCB contamination is widespread usually because of historical sources. Areas with traceable contamination and areas of special concern are being addressed through programs such as the Great Lakes Legacy Act, Superfund or the Resource Conservation and Recovery Act.

Mercury contamination is ubiquitous because of aerial deposition from local, regional and global sources. Thus, solving the problem of mercury contamination Are fish safe to eat?

While most Ohio sport fish are safe to eat, low levels of chemicals like PCBs and mercury have been found in some fish from certain waters.

To help protect the health of Ohioans, Ohio EPA in conjunction with the Ohio Department of Health offers an advisory for how often these fish can be safely eaten. An advisory is advice and should not be viewed as law or regulation. It is intended to help anglers and their families make educated choices about where to fish, what types of fish to eat, how to determine the amount and frequency of fish consumed and how to prepare fish for cooking.

By following these advisories, citizens can gain the health benefits of eating fish while reducing their exposure to unwanted contaminants.

requires solutions on a broader scale than at a watershed level. Ohio is targeting mercury from consumer products such as switches and thermometers through legislation banning the sale of such products. Ultimately, increases in renewable energy sources and clean coal technology usage will lessen Ohio's mercury burden.

Fish populations contaminated by hexachlorobenzene, DDT or mirex are already in the process of being restored through various initiatives in state and federal waste remediation programs.

The recreation analysis focuses on the amount of bacteria in the water. For Lake Erie public beaches, the frequency of swimming advisories varies widely, ranging from near zero at South Bass Island State Park and Battery Park beach to nearly 40 percent or more at Arcadia, Bay View West, Edson Creek, Euclid State Park, Lakeshore Park, Lakeview, Sherod and Villa

Angela State Park beaches. Generally, beaches located near population centers tend to have the most problems.

Beaches on the Lake Erie islands are nearly always suitable for swimming. Several beaches stand out as consistently good performers over the past several recreation seasons including Battery Park, Bay Park,

Catawba Island, Conneaut, East Harbor State Park, Kelleys Island, Lakeside and South Bass Island State Park. These beaches rarely exceeded the goal of fewer than 10 days per season under advisement.

There were also several beaches that performed consistently poorly with four beaches including Bay view East, Edson Creek, Lakeview and Villa Angela beaches under advisement approaching or over 50 percent of the time during the past five recreation seasons.

For inland streams, approximately half of the total assessment units (AUs) (watershed and large river) had sufficient data to determine the recreation use assessment status in 2016. Of the

Is water safe to drink?

Public water systems around the state and Ohio EPA work hard to ensure that the water provided meets safe drinking water standards and to make important information available about the sources and quality of the water you drink. However, drinking water advisories do occur from time to time due to treatment plant malfunctions, water line breaks, and the rare case when source water contaminant levels exceed the plant's capacity to remove them. It is important to remember that only a relatively small number of water systems have situations that warrant advisories. In 2010, 99 percent of all public water systems met all chemical standards. In order to get information about your local drinking water you can read the Consumer Confidence Report (CCR) provided annually by your community water system.

In this report several waters are identified as impaired due to elevated nitrate or pesticides. Water systems in these areas and others with source water contaminants will issue public notice advisories or use additional treatment and water management strategies to assure that safe water is delivered to their customers.

Is it safe to swim or wade?

For the most part, water in Ohio is safe for swimming or wading. Water activities are more dangerous after heavy rains due to the obvious physical dangers of being swept into the faster flows, but also because chemicals and bacteria wash into the streams along with the water that runs over the land. In some communities, sewage systems cannot handle the extra volume of water and release untreated sewage during and after heavy rains.

There are some areas where the waters and/or sediments have high levels of contaminants, including PCBs and polyaromatic hydrocarbons (PAHs), so swimming or wading in these areas is not recommended.

watersheds assessed, 10 percent fully supported the use while 90 percent did not.

Increased bacteria levels are often observed during periods of higher stream flows associated with heavy rains. Although not sampled as frequently as streams or Lake Erie beaches, bacteria levels at most inland lake beaches do not frequently exceed the threshold, resulting in fewer postings compared to some of the beaches along Lake Erie.

Human health impacts related to drinking water focus on nitrate, pesticides and cyanotoxin (due to certain algae). There are a total of 119 public water systems using surface water (excluding Ohio River intakes). Sufficient data were available to evaluate 43 percent of the drinking water source waters for nitrate.

The only nitrate impaired areas were the Maumee River (the systems for the communities of Defiance, Napoleon, McClure, Wauseon, Bowling Green and the Campbell Soup system) and a portion of the

Sandusky River (Fremont). Some areas were identified for a watch list; most were located in the northwestern and central parts of the state. It is difficult and expensive to remove nitrate from drinking water; some systems are conducting nitrate removal pilot studies, but no Ohio surface water systems currently use treatment specific for nitrate removal. Ohio public water systems rely on blending the surface water with other sources such as ground water, selective pumping from the stream to avoid high nitrate levels by using off-stream storage in upground reservoirs or issue public notice advisories warning sensitive populations to avoid drinking the water while nitrate levels are high.

Pesticides could be evaluated for about 21 percent of the drinking water source waters. Five of 19 WAUs were identified as impaired, all in southwestern Ohio: one in Brown County (Mt. Orab); one in Miami County (Piqua); and the three sources used by the Village of Blanchester in Warren and Clinton counties. Eighteen areas were identified for a watch list because of elevated atrazine.

Since the end of the last report cycle, incidents of harmful algal blooms (HABs) impacting Ohio public drinking water supplies have greatly increased. Sufficient data were available to list 19 AUs (15 percent) as impaired. The impairment listing includes the entire Lake Erie Western Basin shoreline, Lake Erie Central Basin shoreline and Lake Erie Island shoreline AUs. In addition, 15 WAUs are now assessed as impaired. These include water supply sources in Lima (Allen County); Bowling Green (Wood County); Clyde (Sandusky County); Norwalk (Huron County), Akron and Barberton (Summit County); Woodsfield (Monroe County); Cadiz (Harrison County); Celina (Mercer County); the Wyanoka Regional Water District (Sardinia – Brown and Harrison Counties); and Clermont County. One large river AU was identified as impaired for algae: Maumee River Mainstem in Bowling Green (Wood County). Sixteen WAUs and three LRAUs are on the algae watchlist.

The bulk of the new data evaluated for the **aquatic life use** is in areas Ohio EPA sampled during 2013 and 2014. Watersheds intensively monitored during 2013 and 2014 included the St. Joseph River, the Tiffin River, the lower Mahoning River, Wolf/Olive Green/Meigs/Rainbow Creeks, Bokes Creek, Stillwater River, the lower Auglaize River, the Rocky River, Wills Creek, Big Darby Creek and Southwest Ohio River Tributaries (Mill, Muddy, Bullskin and Twelvemile Creeks). Detailed survey reports for many of these watersheds are or will be available at http://epa.ohio.gov/dsw/document_index/psdindx.aspx.

Large rivers are making progress towards the "100% attainment by 2020" aquatic life goal.

			Percent of Aquatic Life Standard			
Stream	Year Studied	Percent of Stream Monitored	Meeting	Partially meeting	Not meeting	Not known
Mahoning	1994	100	0	0	100	0
River	2013	100	45	45	10	0
Tiffin	1992	100	0	100	0	0
River	2013	100	100	0	0	0
Stillwater	2010	100	93	7	0	0
River	2013	100	95	5	0	0
Wills	1994	100	16	84	0	0
Creek	2014	100	55	45	0	0
Cuyahoga	2008	77	70	20	10	0
River	2014	95	69	17	14	0

Ohio's large rivers (the 23 rivers that drain more than 500 square miles) reflected a small decline in percent of monitored miles in full attainment compared to the same statistic reported in the 2014 IR. The "100% full attainment by 2020" aquatic life goal

statistic now stands at 87.4 percent (1063 of 1216 assessed LRAU miles), down 1.8 percent from the

2014 IR. The table above shows the status of the five large rivers recently sampled. Taken collectively since the 1980s, the quality of aquatic life in all of Ohio's large rivers has shown a remarkable improvement. Then, only 21 percent of the large rivers met water quality standards, increasing to 62 percent in the 1990s, to 87.4 percent today.

Areas not meeting the standards have decreased from 79 percent in the 1980s to 38 percent in the 1990s to 14 percent today. Across Ohio, investment in the treatment of municipal and industrial wastewater and improvement in agriculture conservation practices are credited with the turnaround. The substantial aquatic life improvements observed in these rivers over the last 25 years directly correlate to implementation of agricultural best management practices and upgraded wastewater treatment plants. The ability to track these water quality trends attests to the value of consistent monitoring over time. The following figure shows percent attainment status and goal progress ("100% by 2020") for monitored miles of Ohio's LRAUs.

For Ohio's 1,538 12-digit HUCs, the score calculated from measurements at individual sites also continued its steady increase, although with an average score considerably lower than the large river full attainment statistic. Watershed scores are roughly equivalent to the percent of sites within the

watershed unit that are meeting biological expectations and the designated aquatic life use, but some additional weight is given to results from larger stream sites in the unit. Based on monitoring through 2014, the average watershed score is now 61.5 (of watersheds with data), up from 59.2 in 2014. Of the 983 watershed units assessed for this report with current data, 507 (52 percent) scored 80 or above and 420 (43 percent) scored perfect 100s. The graph above shows the average full attainment watershed score for monitored HUC 11 WAUs during reporting cycles from 2002 to 2010 and HUC 12 WAUs during reporting cycles from 2010 to 2016.

The collection of more biological data along the shore of Lake Erie as a result of the Great Lakes Restoration Initiative allows a more current analysis of shoreline conditions. The aquatic life use of the Lake Erie shoreline is impaired due primarily to tributary loadings of nutrients and sediment, aggravated by the proliferation of exotic species, algal blooms and shoreline habitat modifications.

Most aquatic life impairment is caused by land disturbances related to agriculture activities and urban development.

Taking a closer look at the attainment status of individual sites grouped by the amount of land area drained by the stream at that point reveals that unhealthy fish and aquatic insect populations are more common on smaller streams (see chart to the left). In other words, the larger the drainage area (and usually the larger the stream), the more likely the stream is to be healthy. This phenomenon

correlates well with the most widespread causes associated with the aquatic life impairment in these watersheds.

The top five aguatic life impairment causes for the period 2003 through 2014 are:

- siltation/ sedimentation
- nutrients
- habitat modification
- hydromodification
- organic enrichment/ dissolved oxygen (DO)

For watersheds, most impairment is related to modification of the landscape. These types of impairments have the most impact on smaller streams. Most of the impaired watershed units with current data had at least one of these causes contributing to impairment and many had two or more of the top five causes listed.

Of note is the prevalence of watersheds and large rivers that are impaired by the generic organic

enrichment/DO cause category; 30 percent of impaired watersheds show "sewage" related impairments such as high biochemical oxygen demand, elevated ammonia concentrations and/or in-stream sewage solids deposition. This suggests that adequate treatment and disposal of human and animal wastes via wastewater treatment plants; home sewage treatment systems; and land applications of septage and animal manure continue to be critical water quality issues in many Ohio watersheds. The major causes and sources of water quality problems are described below.

Organic enrichment is the addition of carbon-based materials from living organisms beyond natural rates and amounts. Natural decomposition of these materials can deplete oxygen supplies in surface waters. Dissolved oxygen (DO) is vital to fish and other aquatic life and for the prevention of odors associated with the decomposition process.

Siltation/sedimentation describes the deposition of fine soil particles on the bottom of stream and river channels. Deposition typically follows high-flow events that erode and pick up soil particles from the land. Soil particles also transport other pollutants. As the flow decreases, the soil particles fall to the stream bottom. This reduces the diversity of stream habitat available to aquatic organisms.

Habitat modification is the straightening, widening or deepening of a stream's natural channel. Habitat modification can also include the degrading or complete removal of vegetation from stream banks; such vegetation is essential to a healthy stream. These activities can effectively transform a stream from a functioning ecosystem to a simple drainage conveyance. Some aquatic life will not be protected from predators and stressful flows and temperatures. The stream also often loses its ability to naturally process water pollutants.

Hydromodification, or flow alteration, describes any disruption to the natural hydrology of a stream system. Flow alteration includes stream impoundment, increased peak flows associated with the urbanization of watersheds and watertable regulation through sub-surface drainage. Such changes can cause extended periods without stream flow, more extreme or frequent floods and loss of fast current habitat in dam pool areas.

Contamination by pathogens occurs when human or animal waste reaches the stream. Pathogenic organisms include bacteria, viruses and protozoa. Contamination by pathogens is a human health issue, as skin contact or accidental ingestion can lead to various conditions such as skin irritation, gastroenteritis or other more serious illnesses.

Nutrient enrichment describes the excess contribution of materials such as nitrogen and phosphorus used for plant growth. Excess nutrients are not toxic to aquatic life, but can have an indirect effect because algae flourish where excess nutrients exist. The algae die and their decay uses up the dissolved oxygen that other organisms need to live. The aquatic community is stressed on both a daily basis and over the long term.

The same nutrients that cause impairment of the aquatic life beneficial use also are a major contributing factor to the recent extensive HABs that have been observed in Lake Erie, the Ohio River and many inland Ohio water bodies. Grand Lake St. Marys in western Ohio has been particularly affected. HABs, a visually identified concentration of cyanobacteria, can occur almost anywhere there is water: lakes, ponds, storm water retention basins, rivers, streams or reservoirs.

Many HAB-forming organisms are native to Ohio, but only cause problems when environmental conditions favor them. HABs can cause taste and odor problems in drinking waters; pollute beaches with scums; reduce oxygen levels for fish and other animals; cause processing problems for public water supplies; and may generate toxic chemicals. Knowing what triggers HABs is key to reducing their occurrence and impacts. HABs may be minimized, and some completely avoided, by reducing the nutrients and pollutants added to the water.

Understanding how various land uses impact water quality can lead to more effective prevention and restoration.

Ohio has embraced a wide variety of economic enterprises over the past 150 years, so it is not surprising that there is a large variety of causes and sources of impairment some of which are described below.

Row crop cultivation is a common land use in Ohio. Frequently, cultivated cropland involves tile drainage. The challenge is to carry out actions that improve water quality while maintaining adequate drainage for profitable agriculture. The land application of manure, especially during winter months, is often a large source of both bacteria and nutrients entering streams and subsurface drainage tiles. Many cropland practices involve the channelization of streams, which creates deeply incised and straight ditches or streams. This disconnects waterways from floodplains, which has

damaging impacts on the quality of the system. The regularity of the stream channel and lack of instream cover reduces biological diversity.

Land development is the conversion of natural areas or agriculture to residential, industrial or commercial uses. Numerous scientific studies show that increasing impervious cover (i.e., hard surfaces such as roads, parking lots, and rooftops) harms water quality. More water runs off the hard surfaces and more quickly. The rate of erosion increases and streams become unstable. The resulting channel is less able to assimilate nutrients and other pollution. Higher runoff volume increases the amount of pollutants (e.g., nutrients, metals, sediment, salts and pesticides). Another problem is that stream

temperatures can be raised when water runs over hot pavement and rooftops or sits in detention basins. When this heated water enters a stream, the higher temperatures reduce dissolved oxygen

concentrations that aquatic life need to survive. With proper planning of development, many of these problems can be mitigated or avoided entirely.

Agricultural livestock operations can vary widely in how they are managed. Pasture land and animal feeding operations can be sources of nutrients and pathogens. Frequently livestock are permitted direct access to streams. Direct access not only allows the input of nutrients and pathogens, but also erodes the stream bank, causing excess sediments to enter the stream and habitat degradation. The most critical aspect of minimizing water quality impacts from any size animal feeding operation is the proper management of manure in terms of application and storage.

Industrial and municipal point sources include wastewater treatment plants and factories. Wastewater treatment plants can contribute to bacteria, nutrient enrichment, siltation and flow alteration problems. Industrial point sources, such as factories, sometimes discharge water that is excessively warm or cold, changing the temperature of the stream. Point sources may contain other pollutants such as chemicals, metals and solids.

Acid mine drainage impacts streams with high levels of acidity (low pH); high metal concentrations; elevated sulfate levels; and/or excessive dissolved and suspended solids and/or siltation. Acid mine drainage often has toxic effects on stream organisms and degrades habitat quality when deposited metals form a crust on the stream bed and susceptible soils erode from areas disturbed from mining. Ultimately it reduces biological diversity, eliminates sensitive aquatic life, and lowers ecosystem productivity.

Solving Ohio's water quality problems will require collaboration and creativity.

Most of Ohio's water quality problems will not be solved by issuing a permit or building a new wastewater treatment system to treat point sources of pollution. Improving Ohio's surface water quality will require effectively managing land use changes to ensure that polluted runoff is either captured and treated or allowed to infiltrate through the soil before running off into a stream. Restoring and protecting natural stream functions so that pollutants may be more effectively assimilated

by streams is also critical. These actions will require various programs and people working collaboratively on local water quality issues and concerns. Local educational efforts and enhanced water quality monitoring will also play important roles if we are to see significant water quality improvements throughout Ohio.

Many areas of the state are benefitting by the participation of individuals and organizations in local watershed organizations. Some of these organizations have been active for quite some time and are successfully influencing local land use decision making and implementing projects designed to improve water quality in their watershed. Since 2000, Ohio EPA has worked in conjunction with the Ohio Department of Natural Resources (ODNR) to provide section 319(h) grant funding assistance to hire local watershed coordinators to help facilitate the development of watershed action plans. In recent years, the emphasis has shifted from developing plans to implementing water quality improvement projects such as stream restoration, dam removals, agricultural best management practices and others. Ohio EPA is measuring improvements resulting from these projects; however, there remain challenges associated with changing land use decisions and finding cooperative partners.

Ohio EPA is also actively working with ODNR and the Ohio Department of Health (ODH) to protect people from toxins produced by cyanobacteria that may be in recreational waters at concentrations that can affect human health. The strategy outlines thresholds for identified algal toxins, establishes monitoring protocols and identifies the process for posting and removing recreation use advisories. Furthermore, a web site was established to provide background information about HABs; tips for staying safe when visiting public lakes; links to sampling information and current advisories; and contact information for reporting suspected HABs. A link to this website is at the end of this section.

The report provides more detail, including Ohio's Section 303(d) list of impaired waters, as required by the Clean Water Act.

This overview is intended to provide a summary of water quality conditions, progress and challenges in Ohio; it is only the first section of the much larger and more detailed 2016 Integrated Report.

The opening sections of the report describe the universe of water quality in Ohio—the size and scope of Ohio's water resources, programs that are used to evaluate and improve water quality and funding sources for water quality improvement.

The middle sections are more technical and explain the beneficial uses assigned to Ohio's waters; the assessment methodologies used for the analyses of those uses; the data used to determine whether those uses are being supported; and the conclusions drawn about water quality conditions in each AU.

The closing sections describe how waters found to be impaired will be scheduled for further study. A collection of maps that illustrate current conditions and future plans follow the text. The report concludes with summary tables of various types. The 303(d) list is contained in Section L4. Summaries of the condition of each AU are available through the "Interactive Maps" link at http://epa.ohio.gov/dsw/tmdl/OhioIntegratedReport.aspx.

В

Ohio's Water Resources

B1. Facts and Figures

Ohio is a water-rich state bounded on the south by the Ohio River and the north by Lake Erie. These water bodies, as well as thousands of miles of inland streams and rivers and thousands of acres of lakes and wetlands, contribute to the quality of life of Ohio's citizens. The size and scope of Ohio's water resources are outlined in Table B-1.

The larger water bodies included in Table B-1 comprise the major aquatic resources that are used and enjoyed by Ohioans for water supplies, recreation and other purposes. The quality of these perennial streams and other larger water bodies is strongly influenced by the condition and quality of the small feeder streams, often called the headwaters. Approximately 28,900 miles of the over 58,000 miles of stream channels digitally mapped in Ohio are headwater streams. However, the digital maps currently available for Ohio do not include the smallest of headwater channels. Results of a special study of primary headwater streams (drainage areas less than 1 mi²) place the estimate of primary headwaters between 146,000 to almost 250,000 miles (Ohio EPA 2009). Some of these primary headwater streams are in fact perennial habitats for aquatic life that supply base flow in larger streams. This illustrates the importance of taking a holistic watershed perspective in water resource management.

The named streams and rivers that are readily recognized by the public are mostly those that drain more than 50 mi². These 254 principal streams and large rivers in Ohio (comprising 5,679 linear stream miles) are listed by major Ohio watershed in Table B-2. Figure B-1 graphically depicts the extent of these stream and river miles within Ohio.

Ohio is an economically important and diverse state with strong manufacturing and agricultural industries. Many of the historical patterns of environmental impact in Ohio are related to the geographical distribution of basic industries, land use, mineral resources and population centers. Also important, however, is an understanding of Ohio's geology, land form, land use and other natural features as these determine the basic characteristics and ecological potential of streams and rivers. Ohio EPA bases the selection; development and calibration of ecological; toxicological; and chemical/physical indicators on these factors. These indicators are then used via systematic ambient monitoring to provide information about existing environmental problems; threats to existing high quality waters; and successes in abating water pollution problems in Ohio's surface waters.

Fourteen river systems in Ohio are included in the State Scenic Rivers Program, administered by the Ohio Department of Natural Resources (see Figure B-2). Between 1970 and 2008, a total of 674 miles were designated Scenic; 75 miles in three systems were designated Wild; and 79 miles in two systems were designated Recreational. Portions of three stream systems—the Little Miami, Little Beaver Creek and Big and Little Darby Creek—are also included in the National Wild and Scenic System. The total Ohio stream miles included in the national designation is 207 miles. More information on Ohio's scenic rivers can be found at http://watercraft.ohiodnr.gov/scenicrivers.

B2. 2020 Water Quality Goals

As has been shown, Ohio has a variety of high quality water resources. Ohio has set goals to track trends in water quality for many years. In the early 1990s, Ohio EPA established a goal of fully attaining the designated aquatic life use¹ in 80 percent of Ohio's streams and rivers by 2010. The purpose of the goal was not to supersede the Clean Water Act goal of 100 percent attainment for all uses, but rather to provide a reasonable target against which to track water quality improvements in Ohio. The 2010 Integrated Report marked the final accounting of "80 by 2010" goal progress and proposed new goals for the aquatic life beneficial use.

New goals for all four beneficial uses included in the Integrated Report (IR) were established in the 2012 report. Progress toward these goals is discussed in each IR cycle. Table B-3 lists the goal, the statistic that will be tracked to measure progress and the baseline and current status for each goal. See Section G for more information about the aquatic life use goal.

¹ Beneficial use designations describe existing or potential uses of water bodies. See Section D4 for additional description.

Table B-3. 2020 goals for four beneficial uses, Lake Erie and the Ohio River.

C

Managing Water Quality

Ohio EPA and other state government departments are directed by the Ohio General Assembly to manage Ohio's water resources. The U.S. Environmental Protection Agency (U.S. EPA) has also delegated to Ohio EPA the responsibility to administer certain federal programs in Ohio.

The functions of various water quality management programs are explained in this section, along with a description of some funding expenditures for water quality activities in Ohio. Some federal government programs are included. Local government programs and decisions (e.g., ordinances, planning and zoning) can have major impacts on water quality, but are not described here.

C1. Program Summary – Surface Water

The goal of Ohio EPA's Division of Surface Water (DSW) is to restore and maintain Ohio's water resources. This goal reflects the national water quality objective as contained in the federal Clean Water Act (CWA), which is "... to restore and maintain the chemical, physical and biological integrity of the Nation's waters"—often referred to as the "fishable/swimmable goal." Fishable/swimmable waters are resources that support stable, balanced populations of aquatic organisms that are ecologically "healthy" and provide safe water to the people of Ohio for public and industrial water supplies and recreation.

DSW has a full time staff of approximately 200 located in Columbus and the five Ohio EPA district offices. The division also employs approximately 50 interns during the summer to assist with biological and chemical water quality surveys. Funding for the division is comprised of federal monies, environmental protection funds generated through solid waste dumping fees and annual discharge fees.

A watershed-based approach to assessments and delivery of services has been a program management objective within DSW for nearly two decades. In 1990, DSW initiated an organized, sequential approach to monitoring and assessment (the "Five-Year Basin Approach") to better coordinate the collection of ambient monitoring data so that information and reports would be available in time to support water quality management activities such as the issuance of National Pollutant Discharge Elimination System (NPDES) permits and periodic revision of the Ohio water quality standards (WQS).

To establish the framework, the State was divided into 25 different areas that were aggregations of subbasins within major river basins. Each of the 25 areas were assigned to one of the five basin years, taking into account the need to appropriately distribute the monitoring workload among Ohio EPA's five district offices. The initial 1990 workload estimates and resource planning indicated that five years would be needed to complete the cycle of monitoring. However, the monitoring program has never been fully funded to meet those resource needs and thus the monitoring cycle takes more than 10 years to complete.

The Five-Year Basin Approach and the core work of the biological and water quality monitoring program have gradually become the Division's assessment component within the Total Maximum Daily Load (TMDL) program. Ohio's TMDL program has been designed to be watershed-focused and to promote integration of other ongoing water program elements on a watershed basis.

Biological and Water Quality Surveys

Ohio EPA routinely conducts biological and water quality surveys, or biosurveys, on a systematic basis throughout the state. A biosurvey is an interdisciplinary monitoring effort coordinated on a reach specific or watershed scale. Such efforts may involve a relatively simple setting focusing on one or two small streams, one or two principal stressors and a handful of sampling sites or a much more complex

effort including entire drainage basins, multiple and overlapping stressors and tens of sites.

Each year Ohio EPA conducts biosurveys in four to six major watersheds in Ohio with an aggregate total of 400 to 450 sampling sites. Biological, chemical and physical habitat monitoring and assessment techniques are employed in biosurveys in order to meet four major objectives:

- 1. to provide a current and thorough assessment of water quality conditions in watersheds that are scheduled for TMDLs in the near future (1-3 years);
- 2. to determine the extent to which use designations assigned in the Ohio WQS are either attained or not attained;
- 3. to determine if use designations assigned to a given water body are appropriate and attainable and recommend designations or changes where needed; and
- 4. to determine if any changes in key ambient biological, chemical, or physical indicators have taken place over time, particularly before and after the implementation of point source pollution controls or best management practices (BMPs).

The data gathered by a biosurvey is processed, evaluated and synthesized in a biological and water quality report. The findings and conclusions of each biological and water quality study may factor into regulatory actions taken by Ohio EPA and are incorporated into the Ohio WQS (OAC 3745-1), Water Quality Permit Support Documents (WQPSDs), State Water Quality Management Plans, the Ohio Nonpoint Source (NPS) Assessment and the aquatic life beneficial use analysis in the Ohio Integrated Water Quality Report [this report, prepared to meet the requirements of CWA Sections 305(b) and 303(d)] and TMDLs.

Additional information on DSW's water quality monitoring and assessment program is available at the following web site: http://www.epa.ohio.gov/dsw/bioassess/ohstrat.aspx. An index with links to available biological and water quality reports can be found at the following web site: http://www.epa.ohio.gov/dsw/document_index/psdindx.aspx.

Biosolids

Sewage sludge is the solid, semisolid or liquid residue generated during the treatment of domestic sewage in a treatment facility. When treated and processed for beneficial use, sewage sludge becomes biosolids—nutrient-rich organic materials that can be safely recycled and applied as fertilizer. Only biosolids that meet the standards spelled out in the Federal and state rules can be approved for use as a fertilizer. Publicly Owned Treatment Works (POTWs) make the decision whether to recycle the biosolids as a fertilizer, incinerate it or bury it in a landfill.

Ohio EPA received delegation to administer the Biosolids Program (CWA Section 503 Program) in 2005. In March 2000, House Bill (HB) 197 was passed by the Ohio General Assembly to provide the statutory authority for the director of Ohio EPA to seek delegation of the program. HB 197 modified the Ohio Revised Code (ORC) to provide the director of Ohio EPA the authority to adopt, enforce, modify and rescind rules necessary to implement the Biosolids Program. HB 197 also modified the ORC to include an annual sewage sludge fee in order to fund the program. Each dry ton of sewage sludge, treated or disposed in the State of Ohio, is assessed a fee with a cap of \$600,000 per year on all monies collected. Shortly after the passage of HB 197, Ohio EPA began drafting rules that became effective in April 2002, as Ohio's Sewage Sludge Rules: Chapter 3745-40 of the Ohio Administrative Code (OAC). The purpose of Chapter 3745-40 of the OAC is to "establish standards applicable to the disposal, use, storage, or treatment of sewage sludge or biosolids, which standards are intended to reasonably protect public

health and the environment, encourage the beneficial use of biosolids and minimize the creation of nuisance odors." The most recent version of OAC 3745-40 became effective in July 2011.

Funded by annual sludge fees, Ohio EPA hired employees to cover sewage sludge management duties in the field and office. These employees perform compliance evaluation inspections at POTWs that beneficially use biosolids. They review annual data submitted by POTWs to ensure compliance with pollutant limits, monitoring and reporting requirements and perform authorization inspections at proposed land application sites. Field reconnaissance inspections are conducted at land application sites to verify compliance with site restrictions and management practices. These employees also review the NPDES permits that regulate sewage sludge generators.

Ohio EPA also funded college interns through the annual sludge fees to track authorized biosolids application sites. The interns developed a Geographic Information System (GIS) project to add authorized biosolids sites to a digital base map. Each authorized biosolids site receives a unique identification number through the GIS program. The GIS project is useful for managing the numerous land application sites and associated data such as cumulative pollutant loadings rates or proximity to source water protection areas for public drinking water supplies.

Combined Sewer Overflow Control Program

Combined sewers were built to collect sanitary and industrial wastewater, as well as storm water runoff and transport these combined waters to a wastewater treatment plant (WWTP). During dry weather, they are designed to transport all flow to the WWTP. When it rains, the volume of storm water and wastewater may exceed the capacity of the combined sewers or of the WWTP. When this happens, the combined sewers are designed to allow a portion of the combined wastewater to overflow into the nearest stream, river or lake. This is a combined sewer overflow (CSO). Ohio has approximately 1141 known CSOs in 89 CSO communities (February 2016), ranging from small, rural villages to large metropolitan areas.

In 1994, U.S. EPA published the national CSO Control Policy. Working from the national policy, Ohio EPA issued its CSO Control Strategy in 1995. The primary goals of Ohio's Strategy are to control CSOs so that they do not significantly contribute to violations of water quality standards or the impairment of designated uses and to minimize the total loading of pollutants discharged during wet weather. Ohio's Strategy addresses several issues that aren't covered by the national policy (for example, sanitary sewer extensions that occur up pipe of CSOs).

In 2000, Congress passed the Wet Weather Water Quality Act, which did two important things; it codified the 1994 national policy by making it part of the CWA and it required that all actions taken to implement CSO controls be consistent with the provisions of the national policy.

Ohio EPA continues to implement CSO controls through provisions included in NPDES permits and using orders and consent agreements when appropriate. The NPDES permits for Ohio's CSO communities require them to implement the nine minimum control measures. Requirements to develop and implement Long Term Control Plans (LTCPs) are also included where appropriate. In 2007, U.S. EPA adopted a new definition for the Water Safe for Swimming Measure, which sets goals to address the water quality and human health impacts of CSOs. The new definition sets a goal of incorporating an implementation schedule of approved projects into an appropriate enforceable mechanism, including a permit or enforcement order, with specific dates and milestones for 91 percent of the nation's CSO communities by September 2015. As of December 2014, 81 of Ohio's 89 CSO communities met this

definition (91 percent), meeting the U.S. EPA's Safe for Swimming Measure goal.

Compliance and Enforcement Program

DSW staff works closely with the regulated community and local health departments to ensure that surface waters of the state are free of pollution. The regulated community with which DSW staff works includes wastewater facilities, both municipal and industrial and small, unsewered communities experiencing problems with unsanitary conditions.

DSW staff provides technical assistance, conducts inspections of WWTPs, reviews operation reports, oversees land application of biosolids and manure from large concentrated animal feeding operations and investigates complaints regarding malfunctioning WWTPs and violations of Ohio's WQS. DSW strives to ensure that permitted facilities comply with their NPDES permits. DSW also assists small communities with inadequate means of wastewater treatment to seek alternatives to help abate pollution to surface waters of the state.

Under the NPDES program, Ohio EPA regulates discharges of pollutants from municipal and industrial WWTPs and sewer collection systems; as well as, storm water discharges from industrial facilities and municipalities. Ohio EPA enforces environmental laws, per ORC 6111 and the OAC, to protect human health and the environment and, when warranted, will seek civil or criminal enforcement action against violators to control illegal discharges of pollutants to waters of the state.

In cases where Ohio EPA is unable to resolve continuing water quality problems, DSW may recommend that enforcement action be taken. The enforcement and compliance staff works with Ohio EPA attorneys, as well as the Attorney General's Office, to resolve these cases. All final enforcement orders are posted on DSW's website.

Concentrated Animal Feeding Operations

On December 14, 2000, Governor Taft signed a bill that started the process of transferring authority to regulate concentrated animal feeding operations (CAFOs) to the Ohio Department of Agriculture (ODA), which now regulates construction and operation of large concentrated animal feeding facilities under their Permit to Install (PTI) and Permit to Operate (PTO) programs. However, PTI authority for sewage treatment and disposal systems at animal feeding facilities and for animal feeding facilities that discharge to POTWs remains with Ohio EPA.

Ohio EPA also retains authority for implementing the NPDES permit program for animal feeding operations until the revised delegation agreement with U.S. EPA that has been submitted by Ohio is approved by U.S. EPA. As a result of federal rule revisions and court decisions, only facilities that meet the definition of a CAFO and actually discharge to surface waters of the state are required to apply to Ohio EPA for an NPDES permit.

The CAFO program at Ohio EPA uses a watershed perspective to prioritize work to some degree. The changes in the federal rule resulting in CAFO NPDES permits being required only when a facility discharges limits our need and ability to prioritize permitting by watersheds. However, the status of the watershed is considered in making decisions about enforcement and compliance activities (e.g., supplemental environmental projects may be preferred over penalties; more technical assistance may be focused on TMDL watersheds).

Credible Data – Volunteer Monitoring Program

The program's authorizing legislation was passed and signed by the governor in 2003. Ohio EPA adopted rules in 2006 (OAC Chapter 3745-4) for the program's operation and revised those rules in 2011. The legislation and the rules are explicit in the desire to not only encourage the collection of water quality data by volunteers, but also to ensure that the data are valid and useful for their intended purpose. In other words, the data should be "credible." The rule package bears the name "Credible Data" because of this important feature and because the enabling legislation was referred to as the credible data bill. Thus, the words "credible data" appear in the terminology applied to voluntary monitoring programs that choose to participate.

As envisioned by the legislation, any person with an interest in water quality should have a means to collect certain types of data useful for various inquiries about the quality of the water resource. Ohio EPA's role is to foster and broadly oversee the collection, analysis and use of data collected by such "volunteer" individuals and organizations. To promote scientific validity, Ohio EPA has established specific requirements to participate in the program and to collect data using approved study plans.

The law and the administrative regulations are the basis for establishing three broad categories or levels of data that will be deemed "credible" for distinctly different purposes. The overall premise is that there must be an increasing level of scientific rigor behind the sampling and analytical work as we progress from Level 1 to Level 2 to Level 3.

Level 1's purpose is primarily to promote public awareness and education about surface waters of the state. Level 1 may be appropriate for educators from Soil and Water Conservation Districts (SWCDs), Park Districts, Health Departments, schools or anyone with an interest in Ohio water quality.

Level 2 was designed with watershed groups in mind and may also be appropriate for SWCDs and Health Departments. Level 2 data can be used to evaluate the effectiveness of pollution controls, to conduct initial screening of water quality conditions and to promote public awareness and education about surface waters of the state. Level 2 groups are often in the position to perform the valuable function of monitoring long-term surface water quality trends in a watershed (where Ohio EPA may not have the resources to frequently revisit a particular area).

Level 3 provides the highest level of scientific rigor and methods are equivalent to those used by Ohio EPA personnel. The law limits the director's use of data collected under the credible data program for certain regulatory applications (for example, setting water quality standards and evaluating attainment of those standards) to verified Level 3 data. In other words, data submitted under this program as Level 1 and Level 2 data cannot be used for those regulatory purposes.

As of September 2015, the Agency has approved over 1,000 Qualified Data Collectors and 140 study plans. Ohio EPA has created a web-based portal for data entry and data access (Credible Data Online Application, http://www.epa.ohio.gov/dsw/credibledata/submission_of_data.aspx), available through Ohio EPA's eBusiness Center.

Inland Lakes Program

Ohio EPA initiated a renewed monitoring effort for inland lakes in 2008. This report assesses three of the four beneficial uses that apply to inland lakes: recreation, public drinking water supply and human health (via fish tissue). Ohio EPA is in the process of updating the water quality standards rules for lakes. Once these rule updates are complete, Ohio EPA expects to include an assessment of the aquatic life use for

lakes as a factor in listing watershed or large river assessment units in future CWA Section 303(d) lists. More information about Ohio EPA's Inland Lakes Program may be found in Section I of this report.

Lake Erie Program

Ohio EPA's DSW participates in many Lake Erie and Great Lakes related issues and efforts. The key program areas are implementation of Remedial Action Plans (RAPs) under the Areas of Concern Program and implementation of the binational Lake Erie Lake-wide Action and Management Plan (LAMP). Restoration of Areas of Concern (AOCs) and implementation of the Lake Erie LAMP are focused on reducing the loadings of pollutants and restoring all beneficial uses to these waterbodies. Both programs are described in the Great Lakes Water Quality Agreement (GLWQA) between Canada and the United States and are mandated under the Great Lakes Critical Programs Act amendment to the CWA. The GLWQA was most recently revised in 2012 and the Agency is directly involved in implementing the new goals and requirements contained in the agreement.

Ohio EPA also conducts routine monitoring of Lake Erie (within Ohio's jurisdiction) and is responsible for reporting the Lake's condition and identifying impaired waters under the CWA. Ohio EPA initiated a *Comprehensive Lake Erie Nearshore Monitoring Program* in 2011 with the assistance of a Great Lakes Restoration Initiative (GLRI) grant to develop and implement a comprehensive monitoring program. Ohio's long-term monitoring program includes an assessment of water and sediment quality in the western and central basins at fixed ambient stations located in shoreline (bays) and nearshore areas. Biological monitoring includes tracking of burrowing mayfly¹ populations and calculation of fish index scores at select shoreline locations. The hypoxia/anoxia phenomenon in the Central Basin is also monitored with a series of transects that connect fixed ambient stations to the open waters. Periodic intensive surveys in bays, harbors and estuaries are also done.

This monitoring effort supports Annex 2 in the GLWQA, which calls for development of nearshore monitoring to support an integrated nearshore framework. Annex 4 of the GLWQA addresses nutrients and Ohio EPA's monitoring may also support assessment of the lake ecosystem objectives identified in the agreement. Monitoring will directly support the agency's CWA evaluation of the Lake Erie Assessment Units in the bi-annual Integrated Report (IR). Additionally, long-term monitoring will provide the data needed to evaluate water quality trends, assess the effectiveness of remedial and nutrient reduction programs, measure compliance with jurisdictional regulatory programs, identify emerging problems and support AOC delisting.

Initiated in 2012, Ohio EPA expanded monitoring efforts to support the Lake Erie Charter Boat captain monitoring initiative. This unique public-private partnership engaged a key stakeholder that is directly impacted by the recent harmful algal blooms and declining water quality conditions on the lake. Ohio EPA has continued to provide funding to Ohio State University's (OSU) Stone Lab to manage the project and conduct sample analyses from the Charter Boat sampling initiative.

The Lake Erie Program works with many different Division and Agency programs to fulfill current program obligations. Due to the diverse nature of Lake Erie issues there are often activities that fall outside of the three primary components of the program (i.e., AOCs, Monitoring and LAMP) and meaningful engagement with other programs is essential.

¹ As an indicator organism, the status of mayfly populations can be used to evaluate long term changes in water and sediment quality (Krieger et al, 2004).

Areas of Concern (Remedial Action Plans)

Areas of Concern (AOCs) were initially identified in the early 1980s as the most environmentally degraded areas along Ohio's Lake Erie coast. Annex 1 of the GLWQA calls for restoration of beneficial uses that have become impaired due to local conditions at AOCs through development and implementation of RAPs. In many ways these beneficial use impairments (BUIs) reflect the same general goals as represented in the Ohio WQS, but many have targets that differ from the WQS criteria. The BUIs include: 1) restrictions on fish and wildlife consumption; 2) tainting of fish and wildlife flavor; 3) degradation of fish and wildlife populations; 4) fish tumors or other deformities; 5) bird or animal deformities or reproductive problems; 6) degradation of benthos; 7) restrictions on dredging; 8) eutrophication or undesirable algae; 9) restrictions on drinking water or taste and odor problems; 10) beach closings; 11) degradation of aesthetics; 12) added costs to agriculture and industry; 13) degradation of phytoplankton and zooplankton populations; and 14) loss of fish and wildlife habitat.

One way to track progress in AOCs is to measure how close the areas are to achieving restoration (delisting) targets. Restoration targets have been determined for each of the beneficial uses and the monitoring programs needed to evaluate the targets are now being designed and implemented. In 2014, Ohio EPA developed a new AOC Program Framework and updated the "Delisting Guidance and Restoration Targets for Ohio Areas of Concern." The new Framework and Guidance provide clarity for how the state and local AOC Advisory Committees will work together to implement the needed management actions and remove BUIs and delist the AOC. The guidance also assists in tracking progress toward achieving the stated delisting goals under the Great Lakes Regional Collaboration (GLRC) and the associated Great Lakes Initiative Action Plan.

Ohio EPA and our AOC partners have successfully leveraged funding under the GLRI and from other sources to complete assessments and implement effective restoration projects in the state's four AOCs. Figure C-1 displays the AOCs and major tributaries to Lake Erie; a description of each AOC follows.

Ashtabula River AOC

A series of successful dredging projects in 2006-2007 and 2012-2013 under the Great Lakes Legacy Act (GLLA) Program, the GLRI and other recent dredging by the U.S. Army Corps of Engineers (Corps) were critical actions needed to begin removal of BUIs in this AOC. Remediation of the contaminated sediments is necessary to remove BUIs for restrictions on dredging, degradation of benthos, fish tumors and fish consumption restrictions. To address the fish population and habitat related BUIs, Ohio EPA completed a large habitat restoration project on the 5 ½ Slip in 2012 and a sediment and restoration GLLA project in 2014 in the North Slip at Jacks Marine. In 2014 a significant milestone was reached with the completion of all management actions. The river is rapidly rebounding and in April 2014, three BUIs (fish consumption; fish and wildlife populations; and fish and wildlife habitats) were formally removed. There are now only three BUIs remaining in this AOC. Verification monitoring is needed to assess the effects of remediation and restoration activities including evaluation of the benthos community; fish tumors and other deformities; and characterization of current sediment quality. Once monitoring indicates that the river has responded as anticipated and restoration targets have been achieved, the Ashtabula River will be delisted as an AOC.

Black River AOC

There are nine BUIs in this AOC with one (fish tumors) listed as in recovery and two others ready for removal. U.S. EPA funded development of the Lower Black River Ecological Restoration Master Plan in 2009 and numerous restoration projects and characterization studies identified in the plan have been completed. In July 2015, the AOC was formally re-sized to include just the lower portions of the Black

River mainstem watershed and the French Creek watershed (East and West Braches are now excluded). Also in July 2015, U.S. EPA accepted a list from Ohio EPA and the Local Advisory Committee identifying the remaining management actions. Ohio EPA is working with U.S. EPA and the Black River AOC Advisory Committee and local implementers to complete the remaining projects. Progress in this AOC is accelerating and the local AOC Advisory Committee and partners are committed and energized to remove the remaining BUIs within the next few years.

Figure C-1. Ohio Lake Erie AOCs and major Lake Erie tributaries.

Cuyahoga River AOC

There are nine BUIs in the Cuyahoga River AOC. The entire mainstem is achieving delisting targets for biological populations except in the Rt. 82/Brecksville dam pool, the Gorge Dam pool and in the navigation channel. Addressing the contaminated sediments is a top priority and a significant number of actions are currently underway. The final Environmental Impact Statement (EIS) report for the Route 82 Dam should be finalized later in 2016 with dam removal to follow and other projects are underway to improve habitat in the Cuyahoga River navigation channel. GLLA sediment characterizations studies are now final for the Old Channel and Gorge dam sediments and a feasibility study was completed for the Gorge Dam in September 2015 to determine the costs and steps needed to manage the impounded sediment and to remove the dam. The Cleveland Port Authority is developing a plan to address the Old River Channel sediments in 2016. In 2014-2015, Ohio EPA worked with the local facilitating organization to re-establish the Local Advisory Committee. New leadership has been appointed and the committee and sub-committees are formed. Ohio EPA also received a 2014 GLRI grant for strategic implementation planning within the AOC and this project will continue into 2016 and provide a foundation for the habitat restoration plan for the Cuyahoga AOC. Ohio EPA is working with the local AOC group to identify restoration needs, identify priority management actions and implement those projects.

Maumee River AOC

The Maumee AOC is Ohio's largest and most complicated AOC. Contaminated sediments, nonpoint sources, nutrient loads and habitat loss are all major issues. The Maumee River watershed is a major contributor to the impaired water quality of the western basin which is a priority concern under Annex 4 and the Lake Erie LAMP. An important milestone was reached in September 2015 with the removal of the first BUI (BUI12-added costs to agriculture and industry). There are nine BUIs remaining. A GLLA sediment remediation project and Natural Resource Damage Assessment (NRDA) are currently underway on the Ottawa River and other GLLA characterizations on the mainstem are continuing. These assessments are vital in helping Ohio EPA and the local Advisory Committee determine restoration needs and prioritize management actions. In 2014-2015, Ohio EPA worked with the local facilitating organization to re-establish the Local Advisory Committee. New leadership has been appointed and the committee and sub-committees are working to set the path forward. There is a revitalized sense of purpose and focus on delisting and recent assessments of BUI status under the new targets reveal that we are closer to removing several BUIs than previously thought.

Statewide AOC Projects

Ohio EPA revised the 2014 "Delisting Guidance and Restoration Targets for Ohio Areas of Concern." As the Local AOC Advisory Committees implemented the new targets and guidance, a number of corrections and improvements were identified including updating the Black River AOC boundary. The updated guidance (Version 2) was recently finalized in January 2016 and is available online at http://epa.ohio.gov/dsw/lakeerie/index.aspx#125637033-documents.

<u>Lake Erie Lake-wide Action and Management Plan (LAMP, formerly LaMP)</u>

Annex 2 of the GLWQA addresses binational lake-wide management and specifies that the LAMPs for each of the Great Lakes shall document and coordinate the management actions required in the Annex. Specifically, Annex 2 calls for the following management actions:

- establish lake ecosystem objectives;
- assemble, assess and report on existing scientific information;
- identify research, monitor and other priorities to support management actions;
- conduct surveys, inventories, studies and support outreach efforts;
- identify additional action needed to address priority water quality threats;
- develop and implement lake specific binational strategies; and
- by 2015, develop an integrated near shore framework for implementation.

The Lake Erie LAMP also serves as the primary mechanism for coordinating development and implementation of lake-wide habitat and species protection and conservation strategies as required in Annex 7 (Habitat and Species) of the GLWQA. The Lake Erie LAMP was originally intended to focus on reducing loadings of toxic chemical pollutants to the lake but now also includes strategies for addressing NPS pollutants such as nutrient loadings and habitat alterations as well as other issues affecting water quality such as land uses, invasive species and others. The Lake Erie LAMP is a comprehensive framework that outlines the management actions needed to bring Lake Erie back to chemical, physical and biological integrity. Work to restore the AOCs and implement the LAMP program both support the U.S. EPA Strategic Plan objective 2.2 – Protect and Restore Watershed and Aquatic Ecosystems. Many of the new directives outlined in the 2012 GLWQA will be implemented through the binational LAMP partnership, including the binational nutrient reduction strategy for Lake Erie, the Nearshore monitoring framework and other initiatives. Although the LAMPs are not specifically mentioned in the

GLRC, many of the priorities addressed in the GLRC Strategy report are actions recommended by the LAMP. The Great Lakes Initiative Action Plan more strongly includes the LAMPs and does specifically emphasize the implementation of projects that will address LAMP priorities. It is becoming increasingly evident that local stream water quality targets may not be enough to achieve the restoration and protection of the lake. This requires building a stronger connection between watershed/AOC programs and the lake. Reducing nutrient loads and input from the Maumee River watershed, which have a significant impact on the state of Lake Erie, is a stated priority under the GLRI Action Plan. In fact, the Maumee has been identified as a priority watershed in the most recent GLRI Action Plan.

NPS and beach health issues listed in the GLRC and the GLRI plans are important issues for both the AOCs and the Lake Erie LAMP. Programs such as the CWA Section 319, the Beaches Environmental Assessment and Coastal Health (BEACH) Act of 2000, CSO Long-term Control Plans, NRCS-supported agricultural BMP programs and many others are existing efforts that RAP and LAMP partners must coordinate with to expedite restoration. Since January 2014, Ohio EPA's Lake Erie program has been managed alongside the NPS program, which has strengthened coordination between the two programs.

For both the AOCs and the LAMP, it is imperative to keep the local communities and stakeholders engaged. In Ohio's AOCs, the local communities and partners have played a significant role in obtaining the resources for implementation, providing matching funds and serving as the local sponsor. A reliable, long-term source of funding is essential to continue to fund the administration and outreach costs associated with local coordinator leadership efforts. Public outreach efforts are also needed to better connect the decisions and projects in the watersheds to the environmental condition of the lake.

National Pollutant Discharge Elimination System (NPDES) Permits

To protect Ohio's water resources, Ohio EPA issues NPDES permits. These permits authorize the discharge of substances at levels that meet the more stringent of technology or water quality based effluent limits and establish other conditions related to issues such as CSOs, pretreatment and sludge disposal. This is an overview of the process for issuing individual NPDES permits. The series of steps for a particular permit may vary somewhat depending on the size, nature and complexity of the discharge.

The first step in developing an NPDES permit is acquisition of chemical, physical and biological data from the field and laboratory. In-stream chemical data are collected to determine the effect of the discharge on receiving water and sediment quality. Biological data are collected to determine if the discharge is having an impact on the fish and macroinvertebrate organisms that live in the receiving water. Effluent chemical data are also obtained to establish an accurate portrayal of current discharge conditions. Instream chemical data and stream physical data, such as cross section measurements and flow, are necessary for conducting water quality modeling.

As part of developing effluent limits and monitoring requirements, the water quality standards that apply to the receiving water are determined and federal effluent guidelines are consulted for applicability. Permit conditions are developed to protect the designated use and associated chemical criteria of the receiving stream as well as any applicable technology requirements. Permits are also based on the applicable regulatory requirements to address issues such as new or expanded discharges, CSOs, sludge disposal and industrial pretreatment programs.

In places where a TMDL is in place, or under development, permit limits will also be developed to ensure they do not conflict with the TMDL. Permits may include schedules of compliance to meet the TMDL based limits. Permit writers are included on the TMDL teams and work with permittees and the TMDL

team on permit language necessary to implement the TMDL. This helps ensure there are no gaps between the TMDL results and the permit limits that are imposed.

Nonpoint Source (NPS) Program

The framework for Ohio's NPS Program is provided in Ohio's "Nonpoint Source Management Plan." The updated NPS Management Plan, which outlines strategies and objectives for Ohio's NPS program through 2018, was forwarded to U.S. EPA Region 5 on December 31, 2013. The updated plan includes a description of Ohio's NPS grant funding sources which include: Section 319(h) grants and Ohio's Surface Water Improvement Fund (SWIF). The NPS Management Plan (NSMP) also includes a listing of state, federal and local partners—those on whom we rely to best implement the strategies outlined in the updated plan.

The NSMP plan provides four sections where one can easily understand the strategic vision along with aggressive (yet reasonable) goals and objectives of Ohio's NPS Program over the next five years. These sections include:

- 1. Urban Sediment and Nutrient Reduction Strategies—including recommended practices
- 2. Altered Stream and Habitat Restoration Strategies—including recommended practices
- 3. NPS Reduction Strategies—including practices and management actions to reduce silt, sediment and nutrient losses from agricultural lands
- 4. High Quality Waters Protection Strategies

Ohio's NPS Program currently is administering various GLRI grants, including:

- The Lake Erie Nutrient Reduction Demonstration Project Loss Creek, Sandusky River watershed (Crawford County, Ohio), which expanded into Brandywine/Broken Sword watershed and focuses on agricultural conservation and storm water runoff;
- The Lake Erie Watersheds Nutrient Reduction Project, Phase 2 Loss Creek, Brandywine/Broken Sword Creeks, Indian Run-Broken Sword Creek, Headwaters Sycamore Creek and Greasy Run-Sycamore Creek watersheds (Crawford County, Ohio) with focus on agricultural conservation projects;
- Lye Creek, Blanchard River watershed (Hancock County, Ohio), which has expanded into Eagle Creek watershed and focuses on agricultural conservation practices, riparian restoration and storm water demonstration projects;
- Powell Creek, Auglaize River watershed (Defiance and Putnam counties, Ohio), which focuses
 primarily on agricultural conservation practices and some home sewage treatment system
 work; and
- Maumee River Sediment and Nutrient Reduction Initiative, which includes eight unique subgrants in locations throughout the Maumee watershed in Ohio for projects such as stream restoration, wetland restoration, riparian restoration, an innovative agricultural runoff and reuse project, an innovative channel and drainage water management project and urban storm water bio-retention.

Ohio's NPS Program has recently wrapped up Cuyahoga County and Lucas County (county-specific) Storm water Demonstration grants, where matching SWIF dollars helped to leverage approximately 22 projects in the past several years.

Ohio's NPS program also oversees several other important programs and initiatives. The Ohio Inland

Lakes program is designed to access, evaluate and protect or restore Ohio's inland lakes. The updated NPS Management Plan includes five-year goals and objectives for the Inland Lakes Program. The Ohio NPS program oversees the Healthy Waters Initiative, which implements activities based upon the findings of TMDL reports and action items provided in endorsed watershed action plans. The Ohio NPS program oversees the Ohio Watershed Program. Fifteen years after it was established, the Ohio Watershed Program is in a state of transition. Ohio's Watershed Program is now much more focused on implementing practices identified in TMDLs and endorsed watershed action plans and tracking progress.

Ohio's NPS program is now also overseeing Ohio's Lake Erie Program. This program tracks implementation of RAPs on Lake Erie tributaries designated as "Areas of Concern," supports Lake Erie shoreline monitoring and participates in the development and implementation of the LAMP, a document that outlines and helps coordinate management actions to protect and restore Lake Erie. The updated NPS Management Plan includes five-year goals and objectives for Ohio's Lake Erie Program. The most current version of Ohio's NPS Management Plan is available at: http://www.epa.ohio.gov/Portals/35/nps/NPS_Mgmt_Plan.pdf.

Most of Ohio's population is located in urban areas and, likewise, are located near major rivers that are impacted by hydromodification, riparian corridor losses and inputs from storm sewer. Ohio's NPS Program is committed to partner with communities; to provide leadership and funding for communities; and to use a well-defined hierarchy that prioritizes projects, so that high magnitude causes of impairment are eliminated and impaired streams segments in urban areas are incrementally restored.

Progress toward achievement of Ohio's Section 319(h) grants program goals will continue to be measured as part of Ohio's NPS Monitoring and Assessment Initiative. For the past eight years, Ohio EPA staff has conducted all monitoring (physical, chemical and biological), beginning with baseline monitoring through project completion to determine the effectiveness of Section 319 (h) and SWIF funded NPS projects. This initiative not only provides cost savings and improved data quality, but also relieves grant recipients of a task which was often difficult for them to do properly. This initiative also serves as a very important environmental measure: are NPS-funded projects improving water quality or not?

Pretreatment

The State of Ohio received authorization to administer the Pretreatment Program on July 27, 1983. Ohio EPA has approved 126 municipal pretreatment programs and continues to provide pretreatment training and guidance. Many of these programs, such as Cincinnati's Metropolitan Sewer District and Cleveland's Northeast Ohio Regional Sewer District, are national leaders and are regarded as very strong pretreatment programs.

A goal of Ohio EPA's Pretreatment Program is to permit 100 percent of significant industrial users (SIUs) with control mechanisms to implement applicable pretreatment standards and requirements. Ohio EPA's permit framework is designed to ensure that all SIUs within the state, regardless of the POTW's pretreatment program approval status, are issued permits. Those SIUs in approved pretreatment program POTWs are identified by industrial user surveys. As of June 2015, there are 1,274 SIUs discharging to POTWs with approved programs and 133 (known) SIUs that discharge into pretreatment POTWs without approved pretreatment programs have control mechanisms for a total of 1,407 known SIUs in Ohio.

A highlight of Ohio's pretreatment program is the strong indirect discharge permit (IDP) program. The IDP program permits, monitors, inspects and provides enforcement to the SIUs that discharge into pretreatment POTWs without approved pretreatment programs. By this program, Ohio EPA prevents toxic discharges to these smaller POTWs and thereby reduces the potential of severe environmental harm from these facilities.

Section 208 Plans and State Water Quality Management Plan

Ohio EPA oversees the State Water Quality Management (WQM) Plan. The State WQM plan is a requirement of CWA Section 303 and must include nine discrete elements:

- 1. TMDLs
- 2. Effluent limits
- 3. Municipal and industrial waste treatment
- 4. NPS management and control
- 5. Management agencies
- 6. Implementation measures
- 7. Dredge and fill program
- 8. Basin plans
- 9. Ground water

The State WQM plan is an encyclopedia of information used to plot and direct actions that abate pollution and preserve clean water. A wide variety of issues is addressed and framed within the context of applicable laws and regulations. For some issues and locales, information about local communities may be covered in the plan. Other issues are covered only at a statewide level. Many of the topics or issues overlap with planning requirements of CWA Section 208 (items 3-9 above). The State WQM plan includes, through references to separate documents, all 208 plans in the State.

Local governments typically conduct planning to meet the sewage disposal needs of the community. Ohio EPA has established guidelines for planning that are useful in the context of Section 208 and the State WQM plan. Local governments that follow these guidelines are more likely to have the results of their planning work incorporated into the State 208 plan prepared by Ohio EPA. The Areawide Planning Agencies have established their own operating protocols, committees and processes to involve local governments in shaping their 208 plans.

Under Section 208 of the federal CWA, States may designate regional planning agencies to prepare, maintain and implement water quality management plans. All six Areawide Planning Agencies were able to update their 208 plans in 2011, because of increased funding through the American Recovery and Reinvestment Act of 2009 (ARRA) and the State's biennium budget. Additional updates occur on an ongoing basis. The most recent 208 Plan amendments were approved by U.S. EPA on April 8, 2016.

Section 401 Water Quality Certifications

The CWA requires anyone who wishes to discharge dredged or fill material into the waters of the United States, regardless of whether on private or public property, to obtain a CWA Section 404 permit from the Corps and a CWA Section 401 Water Quality Certification (WQC) from the state. Ohio EPA is responsible for administering the CWA Section 401 WQC process in Ohio.

Rules governing the 401 review process are currently found in OAC 3745-1-05 (Stream Antidegradation), 3745-1-50 through 54 (Wetland Water Quality Standards) and 3745-32-01 through 7 (Section 401 WQCs).

Under Ohio's Antidegradation Review, the director may authorize the lowering of water quality resulting from the discharge of dredged or fill material only after determining that the lowering of water quality will not result in the violation of state water quality standards. This is achieved through 1) conducting an alternatives analysis; 2) intergovernmental coordination with other state and federal resource agencies; and 3) a public involvement process.

Applicants must develop three alternatives for each development: preferred, minimal degradation and non-degradation alternatives. The alternatives analysis is intended to walk applicants through a deliberate process to avoid and minimize impacts to aquatic resources while still achieving the project's purpose and need. Applicants must provide compensatory mitigation for any unavoidable impacts to streams and/or wetlands. The program emphasizes evaluation of physical habitat and bio-criteria to determine potential impacts to water quality and to evaluate potential mitigation sites.

Ohio EPA strongly encourages applicants to engage in pre-application coordination early in the development phase to help identify high quality resources, discuss potential alternatives and identify mitigation obligations. Under state law, the 401 application must contain 10 specific items in order for the technical review to begin. When the application is formally considered complete, Ohio EPA has 180 days to conduct its technical review and either approve or deny the project. An applicant may withdraw the application. All projects are subject to minimum 30-day public comment period. Controversial projects may also require a public hearing.

Nationwide permits (NWPs) are general permits issued by the Corps for certain types of projects that are similar in nature and cause minimal degradation to surface waters of the State. There are currently 49 NWPs. Ohio EPA certified many of the NWPs on March 30, 2012, and April 19, 2012 (subject to conditions). The NWPs must be renewed every five years.

401 staff are assigned a specific region of the state based on Ohio EPA districts. In addition, Ohio EPA has staff dedicated specifically to the review of coal mining and Ohio Department of Transportation (ODOT) projects, as well as the review of stream and wetland mitigation project compliance. Additional staff is dedicated to wetland research in support of the 401 WQC program.

Semi-Public Disposal System Inspection Contracts (HB 110)

Annually, Ohio EPA issues hundreds of permits for the installation and operation of small, commercial/industrial wastewater treatment and/or disposal systems. These may be onsite soil dissipation systems or discharging systems under the NPDES permit program for the treatment and disposal of sewage generated within the operation. To date, there are thousands of these small systems operating in Ohio. These "semi-public" systems may include apartment complexes, small businesses, industrial parks, etc. and, by definition, are basically any system that treats sewage from human activities up to a capacity of 25,000 gallons per day. Because of the magnitude and resources available, many of these systems have the potential of going without regular inspections to determine if they are complying with state rules, laws and regulations and ultimately protecting water quality.

As an aid to support this program, the Ohio General Assembly created Ohio EPA's HB110 Program. The program is a contractual partnership between local health districts and Ohio EPA, whereby local health districts (LHDs) conduct, on behalf of the Agency, inspection and enforcement services for commercial sanitary waste treatment/disposal systems discharging between 0-25,000 gallons per day (semi-publics).

Ohio EPA operates the HB110 Program to better protect the public health and welfare and to protect

the environment. Ohio EPA believes that because of the proximity, the multitude of facilities, and the availability of resources, oversight of operations for sanitary waste disposal at semi-publics may best be accomplished locally by qualified personnel.

To offset costs of local oversight, State law (ORC 3709.085) authorizes LHDs to charge fees for inspection services to be paid by semi-publics.

Inspection Program

In accordance with Ohio EPA's HB110 contracts, LHDs regularly inspect sanitary facilities at semi-publics for compliance with Ohio's water pollution control laws and regulations. Investigations of complaints regarding waste disposal by semi-publics are also accomplished locally.

Ohio EPA also consults with LHDs on the approval of plans and issuance of PTIs for semi-publics. Installation inspections may be performed locally to ensure compliance with Ohio EPA's PTI conditions.

Enforcement Activities

In coordination with Ohio EPA, LHDs may notify entities of noncompliance with Ohio's water pollution control regulations. LHDs are also instrumental in identifying semi-publics installed without PTIs, of which Ohio EPA may not be aware.

Where noncompliance notification and informal requests fail to correct violations, entities may be referred to Ohio EPA for enforcement or the County Prosecutor may bring an action under local nuisance ordinances. All discharges of pollutants in a location where they cause pollution of waters of the state that are unpermitted or in excess of permitted amounts are statutory nuisances under Revised Code 6111.04.

Training Program

Ohio EPA intends to provide periodic training for LHDs. Training programs will focus on sanitary waste disposal for Semi-Public facilities, technical assistance, inspection issues and enforcement case development.

Summary

The HB110 Program is a unique opportunity for Ohio EPA and LHDs to assist one another in achieving the mutual goal of protecting public health and welfare. Through responsible regulation of Semi-Public facilities, the local community will benefit from decreased health risks and the State as a whole will benefit from improvements in water quality. Ohio EPA welcomes the participation of all LHDs.

Storm Water Permit Program

Ohio EPA implements the federal regulations for storm water dischargers. Dischargers currently covered include certain municipalities (Phases I and II of the program) with separate storm sewer systems (MS4s) and those facilities that meet the definition of industrial activity, including construction, in the federal regulations.

In 1992, Ohio EPA issued two NPDES general storm water permits: one for construction activity and the other for all remaining categories of industrial activity. The strategy was to permit the majority of storm water dischargers with these baseline general permits (33 USC Section 1342; OAC Chapter 3745-38). It is estimated that over 38,000 storm water discharges have been granted general permit coverage since that time.

The industrial permit has been renewed four times. The construction permit was renewed in April 2013, for the third time and addresses large and small constructions sites. The application form is one-page and called a Notice of Intent (NOI). Ohio EPA responds to NOIs with approval letters for coverage under one of the general permits or, in limited instances, instructions to apply for an individual permit.

After the baseline general permits were issued, Ohio EPA directed its efforts towards further permitting, compliance and enforcement activities, education and technical assistance. Inspections and complaint investigations for compliance and enforcement have been handled at the district level as resources allow. BMPs and pollution prevention has been the major thrust of education and technical assistance activities.

On the municipal side of permitting, five large and medium municipalities in Ohio submitted applications between November 1991 and November 1993. A work group was formed with the cities to draft acceptable permit language for the municipal permits. BMPs included in a citywide storm water management plan were the primary focus of the permits. The cities of Dayton, Toledo and Akron received their original permits in 1997. Exceptions for Cleveland and Cincinnati were also processed². Columbus received its initial permit in 2000. Permits for Columbus, Toledo and Akron have been renewed twice. Dayton's permit has been renewed three times.

Additional categories of discharges, both public and privately owned, were included in Phase II. U.S. EPA issued Phase II regulations in December of 1999. The Phase II storm water regulations required a general permit for small MS4s be issued by December of 2002 and required applications by March of 2003. Ohio EPA issued two general permits for small MS4s during 2002. One is a baseline permit and the second is for MS4s in rapidly developing watersheds. This latter permit accelerated construction and post-construction measures to protect surface waters from the impacts of high density land use development. Federal regulations allowed small MS4s to apply for individual NPDES permits in lieu of general permit coverage. No small MS4 within Ohio chose the individual permit option. The third generation of the Small MS4 general permit was renewed on September 11, 2014.

On the construction side of permitting, Ohio EPA has begun to develop and issue watershed specific construction permits if recommended by a TMDL. On September 12, 2006, Ohio EPA issued a watershed specific construction permit for the Big Darby Creek watershed and this permit was renewed on October 1, 2012. On January 23, 2009, Ohio EPA issued a watershed specific construction permit for portions of the Olentangy River watershed and this permit was renewed on June 2, 2014. These permits contain conditions/requirements that differ from the standard construction permit and each other. Ohio EPA anticipates developing additional watershed specific permits when recommended by TMDLs.

Total Maximum Daily Load (TMDL) Program

The TMDL program identifies and restores polluted waters. TMDLs can be viewed simply as problem solving: investigate the problem, decide on a solution, implement the solution and check back to make

² Phase I federal storm water regulations required permit coverage for municipal separate storm sewer systems (MS4s), which had a MS4 service population of 100,000 or more to obtain NPDES permits. Cleveland and Cincinnati were able to demonstrate that their MS4 service population was less than 100,000 people due to large areas of these cities being served by combined sewers. These two cities were permitted under Phase II of the small MS4 general permit in March 2003. Cleveland and Cincinnati currently have coverage under the third generation Small MS4 general permit.

sure the solution worked. By integrating programs and aligning resources, Ohio is pursuing TMDLs as a powerful tool to develop watershed-specific prescriptions to improve impaired waters.

Ohio uses three key enhancements to the basic federal TMDL requirements to increase the chances that real, measurable improvements in Ohio's water resources will result:

- an initial, in-depth watershed assessment to obtain recent data for analysis of problems and discussion of alternatives;
- implementation actions identified as part of the TMDL with follow-through in permitting and incentive programs such as 319 and loan funds; and
- involving others citizens, landowners, officials, natural resource professionals in the process.

In particular, involving others is critical to restoring waters. Working watershed by watershed, Ohio EPA meets with citizens and landowners to explain the findings of our water quality studies and to identify workable solutions to the problems Ohio EPA has found. Ohio EPA includes other agencies that can improve water resources either by exercising their authority in new ways or through relationships they have already established with critical decision makers. After solutions are identified and recommendations are made, Ohio EPA follows through with meetings with consultants, elected officials and others to ensure that projects continue to completion.

Recent Developments in the TMDL Program

On March 24, 2015, the Supreme Court of Ohio determined that "A TMDL established by Ohio EPA pursuant to the Clean Water Act is a rule that is subject to the requirements of R.C. Chapter 119, the Ohio Administrative Procedure Act. Ohio EPA must follow the rulemaking procedure in R.C. Chapter 119 before submitting a TMDL to U.S. EPA for its approval and before the TMDL may be implemented in an NPDES permit" (*Fairfield Cty. Bd. of Commrs. v. Nally,* 143 Ohio St.3d 93, 2015-Ohio-991 available online at http://www.supremecourt.ohio.gov/rod/docs/pdf/0/2015/2015-Ohio-991.pdf).

Prior to the ruling, TMDLs had been approved by U.S. EPA in approximately 75 percent of Ohio's WAUs, as shown in the "Ohio TMDL Program Progress" map in Section K of this report. By the end of 2015, more than 60 TMDL projects had been approved by U.S. EPA and nearly 40 others are currently being developed. Because none of Ohio EPA's TMDLs have been adopted as rules under Chapter 119 of the Revised Code, the effect of the Supreme Court's ruling is arguably invalidation of all the previously approved TMDLs³ and requires the development of a new process for finalizing any future TMDLs. Ohio EPA is evaluating alternatives for addressing both past and future TMDLs and expects to have a process in place before the next IR is released.

All of the TMDLs are available on Ohio EPA's website at http://www.epa.ohio.gov/dsw/tmdl/index.aspx.

Water Quality Standards (WQS) Program

Ohio's water quality is constantly threatened by many different sources and types of pollution. Under the CWA, every state must adopt water quality standards to protect, maintain and improve the quality of the nation's surface waters. These standards represent a level of water quality that will support the goal of "swimmable/fishable" waters. Water quality standards are ambient standards as opposed to

³ The approved projects included two federal TMDLs completed by U.S. EPA Region 5: Wabash River (05120101 101 and 040) and Mahoning River (05030103 050 and 080). Those TMDLs were not impacted by the Supreme Court decision.

discharge-type standards. These ambient standards, through a process of back calculation procedures known as TMDLs or wasteload allocations (WLA) form the basis of water quality- based permit limitations that regulate the discharge of pollutants into surface waters of the state under the NPDES permit program. The key components of Ohio's WQS (OAC Chapter 3745-1) are described below.

Beneficial use designations describe existing or potential uses of water bodies. They take into consideration the use and value of water for public water supplies, protection and propagation of aquatic life, recreation in and on the water, agricultural, industrial and other purposes. Ohio EPA assigns beneficial use designations to water bodies in the state. There may be more than one use designation assigned to a water body. Examples of beneficial use designations include: public water supply, primary contact recreation and aquatic life uses (warmwater habitat, exceptional warmwater habitat, etc.).

Numeric criteria are estimations of concentrations of chemicals and degree of aquatic life toxicity allowable in a water body without adversely impacting its beneficial uses. Although numeric criteria are applied to water bodies, they primarily are used to regulate dischargers through NPDES permits. To ensure protection of those beneficial uses, Ohio EPA determines maximum acceptable concentrations for over 100 chemicals.

Narrative criteria are general water quality criteria that apply to all surface waters. These criteria state that all waters shall be free from sludge, floating debris, oil and scum, color and odor producing materials, substances that are harmful to human, animal or aquatic life and nutrients in concentrations that may cause algal blooms. Much of Ohio EPA's present strategy regarding water quality based permitting is based upon the narrative free from, "no toxics in toxic amounts." Ohio EPA developed its strategy based on an evaluation of the potential for significant toxic impacts within the receiving waters. Other components of this evaluation are the biological survey program and the biological criteria used to judge aquatic life use attainment.

Biological criteria are based on aquatic community characteristics that are measured both structurally and functionally. These criteria are used to evaluate the attainment of aquatic life uses. The data collected in these assessments are used to characterize aquatic life impairment and to help diagnose the cause of this impairment. The principal biological evaluation tools used by Ohio EPA are the Index of Biotic Integrity (IBI), the Modified Index of well-being (MIwb) and the Invertebrate Community Index (ICI). These three indices are based on species richness, trophic composition, diversity, presence of pollution-tolerant individuals or species, abundance of biomass and the presence of diseased or abnormal organisms. The IBI and the MIwb apply to fish; the ICI applies to macroinvertebrates. Ohio EPA uses the results of sampling reference sites to set minimum criteria index scores for use designations in water quality standards.

Antidegradation policy aims to keep clean waters cleaner than the applicable chemical criteria set by the standards wherever possible. The policy is adopted in rule (OAC 3745-1-05) and describes the conditions under which lowering water quality may be authorized under a discharge permit from Ohio EPA. Existing beneficial uses must be maintained and protected. Water quality better than that needed to protect existing beneficial uses must be maintained unless lower quality is deemed necessary to allow important economic or social development (existing beneficial uses must still be protected).

Public participation is mandated and encouraged in all administrative rule makings including the WQS. Any interested individuals are afforded an opportunity to participate in the process of developing water quality standards. Ohio EPA reviews and, as appropriate, revises water quality standards at least once

every three years. When water quality standards revisions are proposed, the public is notified of these revisions. A public hearing is held to gather input and comments.

Wetland Bioassessment Program

Numerous grants from U.S. EPA over many years have funded work that is advancing the science of wetland assessment methodologies in Ohio. Published work includes an amphibian index of biotic integrity (AmphIBI) for wetlands, a vegetation index of biotic integrity (VIBI) for wetlands and a comparison of natural and mitigation (constructed) wetlands. More recently, reports on an assessment analysis of the association between streams and wetland condition and functions in the Big Run Scioto River watershed, incorporating wetland information with data from other surface water resources to develop a TMDL analysis of a central Ohio watershed and the development of a GIS tool to identify potential vernal pool habitat restoration areas have been made available on DSW's web page: http://www.epa.ohio.gov/dsw/401/ecology.aspx.

DSW recently finalized a report from a U.S. EPA grant to assess the ecological condition of 50 randomly selected natural wetlands across Ohio to generate a "scorecard" of wetland condition. This grant "intensifies" data collected as part of U.S. EPA's National Wetland Condition Assessment conducted across the United States in 2011. Also in progress is a detailed study to improve mitigation success in Ohio, which will include a publicly-accessible GIS website for selecting sites with a high likelihood of achieving ecological success; the creation of a simple soil health assessment tool to better identify sites that may require remediation due to historical soil disturbances; and a survey of reference condition riparian habitats to develop specific ecological performance goals for riparian vegetation restoration projects.

DSW has also recently streamlined its VIBI procedure to simplify data collection, analysis and interpretation, with the goal of enhancing the utility of this assessment as a monitoring tool for wetland restoration projects. The modified procedure, called the VIBI-Floristic Quality (VIBI-FQ), is beginning to be used to monitor compensatory mitigation, 319 grants and contaminated clean-up sites, which have required the establishment of wetland habitat. The initial results have been extremely encouraging.

Wetland Protection Program

Ohio's Wetland Water Quality Standards (OAC 3745-1-50 to -54) contain definitions, beneficial use designations, narrative criteria and antidegradation provisions that guide Ohio EPA's review of projects in which applicants are seeking authorization to discharge dredged or fill material into wetlands. OAC 3745-1-53 gives all wetlands the "wetland" designated beneficial aquatic life use. However, wetlands are further defined as Category 1, 2 or 3 based on the wetland's relative functions and values, sensitivity to disturbance, rarity and potential to be adequately compensated for by wetland mitigation.

Category 1, 2 and 3 wetlands demonstrate minimal, moderate and superior wetland functions, respectively. Category 1 wetlands are typified by low species diversity, a predominance of non-native species, no significant habitat or wildlife use and limited potential to achieve beneficial wetland functions. Category 2 wetlands may be typified by wetlands dominated by native species but generally without the presence of, or habitat for, rare, threatened or endangered species, as well as wetlands that are degraded but have a reasonable potential for reestablishing lost wetland functions. Category 3 wetlands typically possess high levels of diversity, a high proportion of native species, high functional values and may contain the presence of, or habitat for rare, threatened and endangered species. Wetlands that are scarce, either regionally or statewide, form a subcategory of Category 3 wetlands for which, when allowable, only short-term disturbances may be authorized.

The rigor of the antidegradation review conducted under OAC 3745-1-50 through -54 is based on the category of the wetland(s) proposed to be impacted. Category 1 wetlands are classified as Limited Quality Waters and may be impacted after examining avoidance and minimization measures and determining that no significant impacts to water quality will result from the impacts. Category 2 and 3 wetlands are classified as General High Quality Waters and may be impacted only after a formal examination of alternatives and a determination that the lowering of water quality is necessary to accommodate social and economic development. In addition, an applicant must demonstrate that "public need" is achieved in order to receive authorization to impact Category 3 wetlands. Compensatory mitigation ratios are based on wetland category, vegetation class and proximity of the mitigation to the impact site.

C2. Program Summary – Environmental and Financial Assistance

The Division of Environmental and Financial Assistance (DEFA) provides incentive financing; supports the development of effective projects; and encourages environmentally proactive behaviors through two main programs: the Ohio Water Pollution Control Loan Fund (WPCLF) and the Water Supply Revolving Loan Account (WSRLA).

Water Pollution Control Loan Fund

In calendar year 2014, the WPCLF financed a number of municipal wastewater treatment needs, as well as NPS pollution control needs, as enumerated below. Through this program, \$358,978,319 in financing was provided for 103 projects, of which 90 projects were for municipal point sources and 13 projects assisted NPS controls.

The WPCLF financed implementation of 90 municipal wastewater treatment projects costing \$346,119,366. These projects directly addressed sources of impairment for Ohio water resources. 36 of these 90 loans (totaling \$54,962,701) were made to communities with a service population of fewer than 5,000 people.

During calendar year 2014, a total of \$12,858,953 was awarded for 13 NPS pollution control projects. The Water Resource Restoration Sponsor Program (WRRSP) financed seven projects for \$12,522,953 to protect and restore stream and wetland aquatic habitats. Additionally, the WPCLF awarded six direct (principal forgiveness) loans totaling \$336,000 for the correction of failing home sewage treatment systems to economically distressed individuals.

Water Supply Revolving Loan Account

The Water Supply Revolving Loan Account focuses on drinking water supplies. In SFY 2014, the fund made 40 loans totaling \$47,816,507, which included \$17,007,955 to economically disadvantaged communities.

C3. Program Summary – Drinking and Ground Waters

The mission of Ohio EPA's Division of Drinking and Ground Waters (DDAGW) is to "protect human health by characterizing and protecting ground water quality and ensuring that Ohio's public water systems provide adequate supplies of safe water." The division has several programs in place to achieve this mission.

Drinking Water Program

Every Ohioan relies on a safe source of drinking water. DDAGW's Drinking Water Program has jurisdiction over 5,000 public water systems that are required to ensure a safe and adequate supply of drinking water to over 11 million Ohioans.

The Drinking Water Program's functions include overseeing the design and construction of drinking water treatment facilities through plan approval; conducting sanitary survey inspections; administering an operator certification program and a drinking water revolving loan fund; managing compliance monitoring for bacteriological and chemical contaminants; working with public water systems to implement corrective actions when significant deficiencies are identified; developing state rules and guidance for implementing new federal drinking water regulations; and sharing public water system information with the public on the division's web site. Significant interdivision and interagency efforts are being expended to assist public water systems and implement Ohio's Public Water System Harmful Algal Bloom Response Strategy. In 2016, a new section was created in DDAGW to manage and implement both the public water system and recreational HAB response.

Ground Water Program

DDAGW's Ground Water Program maintains a statewide ambient ground water quality monitoring program; shares ground water quality data on the division web site; conducts ground water quality investigations; provides technical support to other Ohio EPA programs by providing technical expertise on local hydrogeology and ground water quality; and protects ground water resources through the regulation of waste fluid disposal in its Underground Injection Program for Class I, IV and V wells.

Source Water Protection Program

Several programs are in place or are being implemented to help protect Ohio's water resources. The Source Water Assessment and Protection Program protects aquifers and surface water bodies that are used by public water systems. A public water supply beneficial use assessment methodology has been developed in conjunction with DSW and it is being implemented.

C4. Program Summary – Environmental Services

For Ohio EPA to protect public health and the environment, Agency staff depends on scientific data to make well-informed decisions. The Division of Environmental Services (DES), Ohio EPA's laboratory, provides most of this data. DES analyzes environmental samples for more than 300 parameters. The laboratory provides chemical and microbiological analyses of drinking, surface and ground water; wastewater effluent; sediment; soil; sludge; manure; air filters and air canisters; and fish tissue.

DES processes approximately 10,000 samples annually, generating approximately 139,500 inorganic and 91,000 organic data points. DES also is responsible for administrating U.S EPA's Discharge Monitoring Report-Quality Assurance Study Program, inspects drinking water and wastewater laboratories and provides technical assistance to Ohio EPA divisions as well as state and local agencies.

C5. Cooperation among State Agencies and Departments

Ohio Water Resources Council

The Ohio Water Resources Council (OWRC), established in statute in 2001, is a forum for policy development, collaboration and coordination for one of Ohio's most important natural resources –

water. The OWRC membership is comprised of an Executive Assistant to the Governor and the directors of the following nine state agencies and commissions:

- Ohio Environmental Protection Agency
- Ohio Department of Natural Resources
- Ohio Department of Health
- Ohio Water Development Authority
- Ohio Public Works Commission
- Ohio Department of Transportation
- Public Utilities Commission of Ohio
- Ohio Department of Agriculture
- Ohio Department of Development

Members of the OWRC meet regularly to work on initiatives and projects that will advance Ohio's strategic goals for water resource management. Two groups assist the OWRC in pursuing its goals. The State Agency Coordinating Group, consisting of staff from the member agencies and the executive director of the Ohio Lake Erie Commission, serves Council members in support and research roles. The Advisory Group, including 20 members appointed by the OWRC and eight technical members representing a variety of stakeholder groups, advise the Council and participate in work groups to develop recommendations on water resource issues. Additional information is available online at http://epa.ohio.gov/dsw/owrc.aspx.

The continued collection of long-term water resources data, effective management of the data and easy access to data and information have been identified as a strategic issue in the OWRC Strategic Action Plan for many years. In 2012, the State Agency Coordinating Group created the Water Quality Monitoring Steering Committee – a small, action oriented group charged with enhancing the effectiveness and use of surface and ground water quality data collected in Ohio. The Committee is composed of ground water and surface water technical or management staff from five state agencies (Agriculture, Health, Natural Resources, Transportation and Environmental Protection) and USGS. Ohio EPA's DSW is the designated lead for the committee.

The first priority identified, and being actively pursued, is to better share and disseminate surface water quality data collected by state agencies. A pilot project with ODNR's Divisions of Oil and Gas and Mineral Resources is underway that would enable sending their surface water quality data to U.S. EPA's STORET database so it would be available through a federally maintained web portal. Once that is accomplished, other Divisions of ODNR (e.g. Wildlife) may be approached to continue this effort. Future plans include developing similar protocols for groundwater data and compliance data and eventually branching out to other significant water quality and quantity data collectors in the state.

Ohio Lake Erie Commission

The Ohio Lake Erie Commission is comprised of the directors of Ohio EPA and the Ohio departments of natural resources, transportation, development, health and agriculture and up to five additional members appointed by the governor. The role of the Commission is to preserve Lake Erie's natural resources, to protect the quality of its waters and ecosystem and to promote economic development of the region. The Commission administers Ohio's Lake Erie Protection Fund, which was established to finance research and implementation projects aimed at protecting, preserving and restoring Lake Erie and its watershed. Since its inception in 1993, the Commission has awarded over 12 million dollars for projects that focus on an array of issues critical to the effective management of Lake Erie and further

the goals of the *Lake Erie Protection and Restoration Plan*. The Fund is supported through tax-deductible donation or purchase of a Lake Erie license plate, which displays the Marblehead Lighthouse or the Lake Erie life preserver. Additional information is available online at http://lakeerie.ohio.gov/.

C6. Funding Sources for Pollution Controls

It is beyond the means of this report to place a dollar value on the environmental improvements gained to date. However, Ohio EPA has documented the recovery of numerous major river segments including the Cuyahoga River, Licking River, Paint Creek and Scioto River. The most successful restoration efforts in Ohio have been those that have combined one or more funding sources to reach water resource goals. Different funding sources are directed towards many different facets of water resource management, so there is always a challenge to pursue and coordinate the different programs at one time. Such coordination takes time and administrative effort to be successful.

There are several funding sources for water quality improvement projects in Ohio. Funding for wastewater and drinking water infrastructure improvement projects is available through Ohio EPA (WPCLF and WSRLA), the Ohio Water Development Authority (OWDA), Ohio Public Works Commission (OPWC), U.S. Department of Agriculture (USDA) Rural Development and the Community Development Block Grant (CDBG) program. An Ohio EPA publication titled, "State and Federal Funding for Drinking Water and Wastewater Systems" details some of these funding sources.

There is also funding available for preservation, conservation and restoration projects that directly benefit water quality. These include the Clean Ohio Fund, Section 319 Grants Program, Surface Water Improvements Fund (SWIF), GLRI, Conservation Reserve Program (CRP) and Ohio EPA's WRRSP. Additional funds from the federal government, as well as the investment in water pollution control measures made by municipal and county governments and the private sector, are the reason for dramatic improvements in water quality in Ohio since the inception of the federal CWA in 1972.

A summary of funding sources, amounts and trends is presented here. The summary is not exhaustive. Efforts have been made to include funding sources not traditionally associated strictly with water quality improvement, but that nevertheless have the potential to positively impact Ohio's water resources.

Clean Ohio Fund

Although not tied directly to measures of water resource improvement, a major Ohio bond fund provides funds for projects that should positively impact water quality in the state. The Clean Ohio Fund, created in November 2000, provides \$400 million over four years for "Brownfield" environmental cleanup projects and "Greenfield" open space and conservation preservation projects. Placed before Ohio's voters as Issue 2 in 2008, the ballot initiative was overwhelmingly approved in all 88 counties, which extended the Fund with another \$400 million bond program. The Fund consists of four competitive funding programs, as described below.

Table C-1. Descriptions of Clean Ohio Fund programs.

Clean Ohio Program	Purpose	Administered by	Funding/year
Clean Ohio Green Space Conservation Program	funds preservation of open spaces, sensitive ecological areas and stream corridors	Ohio Public Works Commission	\$37,500,000
Clean Ohio Agricultural Easement Purchase Program	supports the permanent preservation of Ohio's most valuable farmland through the purchase of development rights	Department of Agriculture	\$6,250,000
The Clean Ohio Trails Fund	improve outdoor recreational opportunities by funding trails for outdoor pursuits of all kinds	Ohio Department of Natural Resources	\$6,250,000
The Clean Ohio Revitalization Fund	cleanup of polluted properties so that they can be restored to productive uses	Ohio Department of Development and Ohio EPA	\$50,000,000

More information about Clean Ohio Fund can be found at https://development.ohio.gov/cleanohio/; information about the Clean Ohio Trails Fund can be found at https://realestate.ohiodnr.gov/outdoor-recreation-facility-grants.

Ohio Water Development Authority

OWDA offers financial assistance for a number of project types, either alone or in conjunction with a state agency (including Ohio EPA). In addition to solid waste, brownfields and emergency programs, OWDA oversees the Fresh Water Program. The Fresh Water Program is a market-based rate program that mirrors the below-market financing available through the WSRLA and the WPCLF (see below). The OWDA 2014 annual report provides an overall summary of loan expenditures for all State of Ohio water and wastewater programs in 2014 (OWDA 2015). More information about OWDA can be found at http://www.owda.org/owda0001.asp?PgID=homepage.

Table C-2. OWDA loans administered during calendar years 2013 - 2014.

	2014		2013		
Project Type	Number	Amount (mil \$)	Number	Amount (mil \$)	% of 2013
Planning					
Water	28	7.1	25	7.8	90.9
Wastewater	55	37.6	36	53.3	70.5
Subtotal	83	44.7	61	61.1	73.6
Construction					
Water	80	135.7	81	175.6	77.3
Wastewater	80	414.2	99	360.0	115.1
Subtotal	160	549.9	180	535.6	103.4
Total	243	594.7	241	596.7	100.4

Water Supply Revolving Loan Account Fund

The Ohio Water Supply Revolving Loan Account (WSRLA) provides an opportunity for mutually beneficial partnerships between Ohio EPA and Ohio's public water systems to assure a safe and adequate supply of

drinking water for all the citizens of Ohio. This is accomplished primarily by providing below-market interest rates for compliance related improvements to community (public) water systems and non-profit non-community public water systems. Additionally, the WSRLA can provide technical assistance to public water systems in a variety of areas from the planning, design and construction of improvements to enhancing the technical, managerial and financial capacity of these systems.

The WSRLA is administered by Ohio EPA's DDAGW and DEFA. Certain financial management services are also provided by OWDA. More information about WSRLA can be found at http://www.epa.ohio.gov/defa/EnvironmentalandFinancialAssistance.aspx.

Water Pollution Control Loan Fund

Municipal wastewater treatment improvements—sewage treatment facilities, interceptor sewers, sewage collection systems and storm sewer separation projects—and nonpoint pollution control projects are eligible for financing under the WPCLF. This state revolving fund, jointly administered by Ohio EPA and OWDA, was established in 1989 to replace the Construction Grants Program. Construction loans from the WPCLF are available at a number of interest rates: a standard rate, which is below market rates; a small community interest rate, which is below the standard interest rate; and 1 percent and 0 percent interest rate loans for hardship communities.

Planning and design loans are available at a short-term interest rate. Applications for WPCLF loans are made to Ohio EPA's Division of Environmental and Financial Assistance. Eligible activities include:

- improvements to and/or expansions of wastewater treatment facilities
- improvement or replacement of on-lot wastewater treatment systems
- brownfield/contaminated site remediation
- agricultural runoff control and BMPs
- urban storm water runoff
- septage receiving facilities
- landfill closure
- septic system improvement
- development of BMPs
- forestry BMPs

More information about WPCLF can be found at http://epa.ohio.gov/defa/ofa.aspx#169558732-water-pollution-control-loan-fund-wpclf--wastewater-collection-and-treatment.

Water Resource Restoration Sponsor Program (WRRSP)

A satellite program of the WPCLF is the Water Resource Restoration Sponsor Program (WRRSP). The WRRSP was developed by Ohio EPA and has been a part of the WPCLF since 2000. The intent of the WRRSP is to address a limited and under-assisted category of water resource needs in Ohio through direct WPCLF loans. The goal of the WRRSP is to counter the loss of ecological function and biological diversity that jeopardize the health of Ohio's water resources. The program achieves this goal by providing funds, through WPCLF loans, to finance implementation of projects that protect or restore water resources, by ensuring either maintenance or attainment of warmwater habitat or higher designated aquatic life uses under Ohio's water quality standards.

Since its inception, over \$160 million has been awarded for water resource restoration and protection through the WRRSP.

Section 319 Grants Program

Ohio EPA receives federal CWA Section 319(h) funding to implement a statewide NPS program, including offering grants to implement local projects to reduce the impacts of nonpoint sources of pollution. Annual funding for local sub grant awards typically averages \$3 million. Section 319(h) grants are awarded for projects such as low-head dam removal, natural stream channel reconstruction, urban storm water infrastructure retrofits, wetland restoration or other projects designed to restore impaired waters. Projects identified in watersheds with TMDLs and/or with endorsed watershed action plans that are aimed at eliminating identified sources of impairment or restoring impaired waters are most likely to receive funding. Other eligible activities include lake management projects and demonstration projects focused on agricultural BMPs that are not typically funded under Farm Bill programs. Nearly all successful grant applications are from watersheds that have either completed an endorsed local watershed action plan or in watersheds where TMDL studies have been completed.

More information about the Section 319 Grants Program can be found at http://epa.ohio.gov/dsw/nps/index.aspx#120843256-for-additional-information.

Federal Farm Bill Funding in Ohio

Among funding sources from the federal government, those conservation programs connected to the "Agricultural Act of 2014" legislation are notable. Administered by USDA, several programs provide cost share, technical assistance and economic incentives to install and/or implement NPS pollution management practices. The 2014 Farm Bill included significant changes in programs such as:

- consolidation of conservation programs for flexibility, accountability and adaptability at the local level;
- linkage of basic conservation practices to crop insurance premium subsidy for highly erodible lands and wetlands; and
- building upon previous successful partnerships and encouraging agricultural producers and partners to design conservation projects that focus on and address regional priorities.

Ohio EPA works closely with Ohio Natural Resources Conservation Service (NRCS) on several water quality related landscape initiatives including: GLRI, the National Water Quality Initiative (NWQI) and the Mississippi River Basin Initiative (MRBI). Ohio EPA has assisted with selecting priority watersheds and practices in these initiatives and provides water quality monitoring.

Set-aside types of programs, such as the Conservation Reserve Program (CRP) and the Conservation Reserve Enhancement Program (CREP), are the most popular of available conservation programs available in Ohio. Targeted acreage through these programs is intended to be environmentally sensitive for land that can have a particularly deleterious impact on natural resources when farmed. Examples include highly erodible land, land near waterways, land that was formerly wetland and lands that can serve as habitat critical to declining wildlife populations. It is a potential concern that once contracts expire on the marginal or environmentally sensitive lands, those acres may revert back to agricultural production.

Conservation Reserve Enhancement Program

The CREP is a federal-state conservation partnership program that is intended to remove environmentally sensitive cropland from production and to convert it to native grasses, trees and other vegetation. The CREP uses financial incentives to encourage farmers and ranchers to enroll in contracts of 10 to 15 years. In return, participants are incentivized annually 150 to 175 percent of crop rental

rates, depending on the type of vegetation planted. Ohio is one of two states in the nation to have three CREP watersheds. Most existing CRP and CREP land retirement program acres involve stream-side grass strips not specifically designed to treat agricultural runoff generated from contributing cropland acreage. There are opportunities to further expand acreage under these programs to include practices that better reduce rate and amount of agricultural runoff. These practices include filter area, wooded riparian corridors and/or wetlands designed to trap, retain, intercept, distribute, store and/or treat runoff from cropland.

Environmental Quality Incentives Program

The Environmental Quality Incentives Program (EQIP) is another widely used, well-funded program coming out of the Farm Bill. EQIP is designed to improve management practices and facilities on working farms to achieve environmental quality goals, of which protecting water resources is a high priority. Several specific practices are eligible for funding through EQIP that cover broad categories such as nutrient and pesticide management and storage, manure management and storage, livestock fencing, conservation tillage, cover cropping, conservation crop rotation and drainage water management, among others. Historically, most EQIP-funded practices in Ohio have gone toward installation of tangible items (e.g., fencing, access roads and manure storage units). Recognizing that NPS pollution from agriculture is largely related to management (e.g., crop rotations and tillage management, or fertilizer application timing, method, rate and form), Ohio-NRCS offered incentive payments to farming operations to adopt a suite of management practices, including conservation tillage, nutrient management plan implementation and cover crops.

Conservation Stewardship Program

The Conservation Stewardship Program (CSP) is a voluntary program that encourages producers to improve conservation systems by improving, maintaining managing and undertaking additional conservation activities. NRCS administers this program and provides financial and technical assistance to eligible producers. CSP offers participants two possible types of payments: annual payment for installation and adoption of additional activities and the improvement, maintenance and management of existing activities; and supplemental payment for the adoption of resource-conserving crop rotations. Such rotations are those that reduce erosion, improve soil fertility and tilth and include at least one resource conserving crop (e.g., perennial grass, legume, or grass/legume grown for use as forage, seed for planting or green manure).

More information on the Agricultural Act of 2014 and related programs in Ohio is available at http://www.nrcs.usda.gov/wps/portal/nrcs/main/national/programs/farmbill/ and http://www.nrcs.usda.gov/wps/portal/nrcs/site/oh/home.

Surface Water Improvement Fund Grants Program

The NPS program continues to administer of the Surface Water Improvement Fund (SWIF) grants program. The SWIF program enhances Ohio EPA's NPS improvement efforts by providing \$1 million to \$3 million per funding cycle (approximately once every two years) in additional funding for locally implemented nonpoint source, stream restoration and innovative storm water management projects. The initial SWIF cycle in 2010 resulted in awarding a total of \$3.45 million to fund 32 individual projects. These grants were provided for projects such as storm water demonstration, stream and wetland restoration, agricultural BMPs and inland lake protection.

SWIF grant funds were also used in fiscal year 2012 to match federal GLRI funds to implement a GLRI SWIF project with specific focus in Cuyahoga County (including Cleveland and its metropolitan area)

where 17 projects were awarded grants totally \$2.05 million. This success spawned a similar project: the Lucas County (including Toledo and its metropolitan area) SWIF in 2013.

For fiscal year 2014, Ohio EPA received 68 applications for SWIF grants. Of the applications received, grants totaling \$1,966,508 were awarded to 19 recipients statewide (except Lake Erie watershed). In the Lake Erie watershed, \$2,195,984 in SWIF grants was awarded to 24 recipients.

More information on the SWIF grants program is available at http://www.epa.state.oh.us/dsw/nps/swif.aspx.

C7. Harmful Algal Blooms Responses and Assessments

Cyanobacteria are photosynthesizing bacteria, commonly called blue-green algae. Some are capable of producing toxins (cyanotoxins) that affect the skin, liver or nervous system. They can also cause water

quality deterioration associated with excessive biomass production (such as depleted dissolved oxygen levels, fish kills, taste and odor problems in drinking water and elevated trihalomethane levels). A large bloom of cyanobacteria that causes harmful effects is called a harmful algal bloom (HAB).

Cyanobacteria have the ability to adapt to a wide range of temperatures and water flow regimes, contributing to their common occurrence across

Ohio waters. The presence of cyanobacteria is not necessarily a concern, but harmful blooms can form when conditions are favorable for rapid growth. When excess nutrients are present, especially phosphorus, these bacteria can form expansive blooms and produce cyanotoxins at levels of concern for humans and animals.

The harmful effects of these blooms are well documented in scientific literature and recognized by U.S. EPA, Center for Disease Control (CDC) and World Health Organization (WHO) as causing acute and chronic

impacts in human and animal populations. U.S. EPA recognizes that HABs are increasing in spatial and temporal prevalence in the U.S. and worldwide and that their highly potent toxins are a significant hazard for human health and ecosystem viability. In early 2015, U.S. EPA issued health advisory levels for two cyanotoxins, microcystins and cylindrospermopsin. Ohio Senate Bill 1 was passed in July 2015 and directed Ohio EPA to implement actions to protect against cyanobacteria in the western basin on Lake Erie and in public water supplies. This legislation led to creation of

Ohio Revised Code 3745.50 authorizing the director to Ohio EPA to serve as the coordinator of harmful algae management and response. Ohio EPA was required to implement actions that manage wastewater and limit nutrient loading and develop and implement protocols and actions to protect against cyanobacteria and public water supplies. Ohio adopted new and revised rules, effective June 1, 2016, to meet these requirements. Cyanotoxins are not currently regulated in recreational waters, however, USEPA is developing national guidance and thresholds that may be issued during the next reporting cycle. In 2016, Ohio EPA created a new Harmful Algal Bloom Section housed in the Division of Drinking and Ground Waters to manage both drinking water and recreational response.

Response to HABs

As incidents of HABs have increased, Ohio's response continues to evolve. The State has annually revised the State of Ohio's Harmful Algal Bloom Response Strategy for Recreational Waters (http://epa.ohio.gov/portals/35/hab/HABResponseStrategy.pdf) and the Public Water System Harmful Algal Bloom Response Strategy. Ohio EPA, ODH and ODNR have continued a close partnership to develop and implement the unified state response strategy. The ohioalgaeinfo.com web site provides background information about HABs; tips for staying safe when visiting public lakes; links to sampling information; and current advisories and contact information for reporting suspected HABs. It also includes historic and current cyanotoxin data for public water supplies and a link to the ODH BeachGuard site, which has information about recreation advisories for both bacteria and algae (http://publicapps.odh.ohio.gov/BeachGuardPublic/Default.aspx).

HAB Recreational Advisories

Advisories are designed to provide information and warnings to protect public health from the potential health impact of cyanotoxins present in HABs. Beginning in 2011, general information signs were placed in areas where HABs have been observed at State Park beaches. These signs encourage beachgoers to be alert for HABs and provide information about their appearance. In addition, the HAB advisory system was changed to a two-level system. A "Recreational Public Health Advisory" (PHA) is posted when toxin levels equal or exceed the established state benchmark criteria. Microcystin is the focus of toxin analysis. When microcystin levels exceed 6 ppb, a PHA is posted. When microcystin levels reach 20 ppb or above then an "Elevated Recreational Public Health Advisory" is posted. Recreational advisory posting and removal protocols are outlined in Ohio's HAB Response Strategy for Recreational Waters. In 2015, the highest level of recreational advisory was a "No Contact Advisory" that required microcystin levels \geq 20 and a confirmed human or animal illness. The numeric thresholds for cyanotoxins in recreational waters remained the same in 2016, but the advisories were changed to "Recreational Public Health Advisory" and "Elevated Recreational Public Health Advisory." The human or animal illness requirement was also removed for the highest advisory (Elevational Public Health Advisory).

In 2013, blooms were reported at eight State Park lakes and three State Park Lake Erie beaches. A bloom was monitored at Buck Creek (C.J. Brown Reservoir) between June 5, 2013, and August 29, 2013, but microcystin levels did not exceed the 6 ppb threshold criteria for recreational waters, so no advisory was posted. In addition, blooms were reported at Lake Alma, Dillon Lake, Madison Lake and Lake Hope State Parks but no advisories were needed. There were four PHAs posted at State Park facilities in 2013. Three of these were for inland lakes (Grand Lake St. Marys, Buckeye Lake and East Fork or Harsha Lake) and one for a beach on Lake Erie as follows:

1. **Grand Lake St. Marys** (PHA posted 5/20/13) – Levels above threshold through 9/24/13 when sampling ceased. The highest microcystin levels were >100 ppb on 5/20/13 and 5/28/13 at Windy Point.

- 2. **Buckeye Lake** (PHA posted 7/31/13) Levels above threshold through 10/16/13 when sampling ceased. The highest microcystin level was 220 ppb at Fairfield Beach on 9/4/13.
- 3. **East Fork** (Harsha Lake) (PHA posted 6/12/13) Levels above threshold through 7/2/13. The highest microcystin level was 88 ppb on 6/12/13. This is the first time that this lake was posted with a PHA.
- 4. **Maumee Bay State Park Beach** (PHA posted 6/4/13) Levels above threshold through 8/5/13. The highest microcystin level was 20 ppb on 6/4/13. Levels then dropped dramatically for most of the summer. Then microcystin spiked at 6.9 on 8/5/13.

Between September 1, 2013, and September 1, 2014, blooms were reported at 12 State Park lakes. Seven other blooms were reported in other waters during this fiscal year. Four of these were in other public lakes; one was in a tributary to the Ohio River; one from Kelleys Island and one from Johnsons Island, Lake Erie.

Table C-3. Bloom reports, PHAs and microcystin levels reported in 2014 (SP = state park).

Table Location	Date	Cyanotoxin
Grand Lake St. Marys	PHA posted 5/20/14	92.8 ppb to >100 ppb microcystins
Jefferson Lake SP	5/28/14	
Indian Lake SP	6/3/14	Non-detect microcystins
East Fork (Harsha Lake) SP	PHA posted 6/18/14	190 ppb microcystins
Alum Creek SP	6/9/14	Non-detect microcystins
Buckeye Lake SP	PHA posted 6/2/14	57-77 ppb microcystins
Acton Lake- Hueston Woods SP	7/7/14	Non-detect microcystins
Chippewa Lake	7/11/14	
Lake Alma SP	7/15/14	Non-detect microcystins
Punderson SP	7/15/14	Non-detect microcystins
Boy Scout Camp lake in Clermont County	7/21/14	
Maumee Bay SP	PHA posted 7/21/14	7.1 ppb microcystins
Lake Hope SP	7/20/14	Non-detect microcystins
Forked Run SP	7/25/14	
Lake Mac-o-Chee Boy Scout Camp	7/29/14	Non-detect microcystins
Bullskin Creek	8/3/14	
Mogadore Reservoir, Portage County	8/6/14	
Kelleys Island	8/22/14	

Of the State Park beaches with blooms tested for microcystins, seven had non-detectable microcystins. There were four PHAs posted at State Park lakes in 2014: 1) Grand Lake St. Marys (GLSM); 2) Buckeye Lake; 3) East Fork (Harsha Lake); and 4) Maumee Bay State Park beaches. ODH reported no probable cases for human or animal illness associated with cyanotoxin exposure in 2014.

Observations 2011-2014

Ohio collected a considerable amount of microcystin and phytoplankton data for Buckeye Lake and GLSM over the past four years. The data show increasing toxin levels in GLSM over this time period (see graphs below). The graphs of the microcystin data for both Buckeye Lake and GLSM show an undulating pattern in microcystin levels (especially for GLSM) showing a release of toxins followed by a period of reduced toxin production and/or toxin degradation.

The data also show that toxin levels can remain elevated into the winter months; ether because there is less toxin degradation in those months and/or there is additional toxin release. For example, on December 11, 2013, there was still 10.3 ppb microcystin detected at the GLSM drinking water intake.

Microcystin levels at Buckeye Lake were higher in 2013 and 2014 than in 2011 and 2012. The 2013 data show a great deal of fluctuation and a couple spikes in microcystin. On June 9, 2014, just at the start of the recreational season, microcystin was already at 19 ppb at Crystal Beach which was above the PHA level. Microcystin data collected by Ohio EPA Central District Office in the open waters of Buckeye Lake showed microcystin levels were also above the PHA threshold.

Some of the highest toxin levels at Buckeye Lake and GLSM occurred in the early spring around the beginning of the 2014 recreational season. For example, on May 9, 2014, there were >100 ppb microcystin detected at the GLSM drinking water intake. On May 20, there were >100 ppb microcystin at Windy Point beach and Camp Beach at GLSM. On May 27, 2014, there were 144 ppb at GLSM Windy Point Beach. There were also some late peak toxin levels, like at Maumee Bay State Park beach where microcystin levels reached 110 ppb on August 4, 2014.

The highest toxin level reported in recreational waters during this time period was 220 ppb at Fairfield Beach at Buckeye Lake. Close behind was 190 ppb at East Fork Campground Beach on June 18, 2014. PHAs were posted at all the State Park beaches at Buckeye Lake and GLSM throughout the 2014 recreational season; however, the East Fork PHA was removed earlier on July 26, 2014.

Euglena sanguinea was reported for the first time in a channel on the south side of GLSM in early September, 2013, about two miles from the drinking water intake. DDAGW sampled the raw and finished water at the drinking water intake about one week after the bloom was observed. Euglena spp. are not cyanobacteria, but are unicellular flagellate protists. This organism is capable of producing the icthyotoxin, euglenophycin, which is extremely toxic to fish and can cause large kills.

The open water samples collected by the Inland Lakes Team showed that high concentrations of potential toxin producing cyanobacteria were not producing cyanotoxins of significance in the open water (see tables in Section I.4.3.1.) *Pseudanabaena* spp., *Aphanocapsa* spp. and *Cylindrospermopsis* spp. were the dominant cyanobacteria in open waters during 2013-2014.

At the present time, Ohio EPA does not list lakes as impaired for recreational use when recreational advisories are posted at public beaches. Addressing water quality impairments in the lake's watershed should eventually reduce nutrient enrichment in lakes and thereby reduce cyanobacteria blooms.

Figure C-2. Microcystin concentration in GLSM during recreational seasons from 2011 to 2015.

Figure C-3. Microcystin concentration in Buckeye Lake during recreational seasons from 2011 to 2015.

Algal Toxin Monitoring and Phytoplankton Monitoring

Monitoring of HABs has occurred in a variety of ways across the state. The main types of monitoring that have taken place are discussed below. Algal toxin monitoring at public water systems is addressed in Section H.

Algal Toxin and Phytoplankton Monitoring by the Inland Lakes Team

The Inland Lakes Monitoring Program continues to collect phytoplankton and microcystin samples from the lakes sampled each year as part of the routine sampling of lakes in TMDL watersheds. Those samples were collected in open water at established sampling locations. In 2013 and 2014, phytoplankton and microcystin samples were collected three times each year. Sampling locations with cyanobacterial cell counts of 100,000 cells/mL or greater of potential microcystin or cylindrospermopsin producers are identified in Tables C7-2 through C7-5 below.

Table C-4. Open water sampling locations in 2013 with cyanobacterial cell counts of 100,000 cells/mL or greater of potential <u>microcystin</u> producers (*= dominant cyanobacteria. *Aphanizomenon* spp. are not included as a potential microcystin producer since there is some disagreement about this).

Lake	Date	Cyanobacteria Genera	Microcystins
Nettle Lake L-2	5/21/2013	*Pseudanabaena	Non-detect
Clendening Lake L-1	5/29/2013	Planktothrix, *Pseudanabaena	Non-detect
Clendening Lake L-2	5/29/2013	*Pseudanabaena	Non-detect
Tappan Lake L-1	5/29/2013	*Pseudanabaena	Non-detect
Tappan Lake L-2	5/29/2013	Anabaena, Planktothrix, *Pseudanabaena	Non-detect
Nettle Lake L-1	7/17/2013	Aphanocapsa, *Pseudanabaena	
Hoover Reservoir L-1	7/18/2013	Anabaena, *Aphanocapsa, Microcystis, Planktothrix, Pseudanabaena	0.47 ppb
Stonelick Lake L-1	9/10/2013	Aphanocapsa, *Pseudanabaena, Anabaena	0.32 ppb
Tappan Lake L-1	10/1/2013	Anabaenopsis, *Aphanocapsa, Microcystis, Pseudanabaena	

Table C-5. Open water sampling locations in 2013 with cyanobacterial cell counts of 100,000 cells/mL or greater of potential <u>cylindrospermopsin</u> producers: (*= dominant cyanobacteria Cylindrospermopsis spp. are known to produce cylindrospermopsin, but this is rarely observed in Ohio).

Lake	Date	Cyanobacteria Genera	Cylindrospermopsin
Hoover Reservoir L-1	7/16/2013	Anabaena, Aphanizomenon, *Cylindrospermopsis	Non-detect
Clendening Lake L-1	9/10/2013	Cylindrospermopsis, Raphidiopsis	
Clendening Lake L-2	9/10/2013	*Cylindrospermopsis, *Raphidiopsis, Anabaena	
Alum Creek L-1	9/10/2013	Aphanizomenon, *Aphanocapsa, Pseudanabaena	
Piedmont Lake L-1	9/10/2013	Anabaena, Cylindrospermopsis, *Raphidiopsis	0.436 PPB
Piedmont Lake L-2	9/10/2013	Anabaena, *Cylindrospermopsis, Raphidiopsis	
Tappan Lake L-1	10/1/2013	* Cylindrospermopsis, Raphidiopsis	
Tappan Lake L-2	10/1/2013	* Cylindrospermopsis, Raphidiopsis	

Table C-6. Open water sampling locations in 2014 with cyanobacterial cell counts of 100,000 cells/mL or greater of potential <u>microcystin</u> producers: (*= dominant cyanobacteria. Aphanizomenon spp. are not included as a potential microcystin producer since there is some disagreement about this).

Lake	Date	Cyanobacteria Genera	Microcystins
Senecaville Lake L-2	7/17/2014	Anabaena, Aphanocapsa,	Non-detect
Sellecaville Lake L-2	7/17/2014	*Pseudanabaena	Non-detect
New Concord Reservoir	7/8/2014	Aphanizominon/Anabaena	Non-detect
	7/15/2014 and	*Aphanocapsa,	
Winton Lake L-1	9/23/2014	Pseudanabaena/Anabaena,	
	9/23/2014	*Aphanocapsa, Pseudanabaena	
Salt Fork Lake L-2	7/16/2014	Aphanocapsa, Pseudanabaena	Non-detect
Hoover Reservoir	8/14/2014	Anabaena, *Aphanocapsa	0.55 ppb

Table C-7. Open water sampling locations in 2014 with cyanobacterial cell counts of 100,000 cells/mL or greater of potential <u>cylindrospermopsin</u> producers: (*= dominant cyanobacteria Cylindrospermopsis spp. are known to produce cylindrospermopsin, but this is rarely observed in Ohio).

Lake	Date	Cyanobacteria Genera	Cylindrospermopsin
New Concord Reservoir L-1	6/17/2014 and	*Aphanizomenon	Non-detect on both
New Concord Reservoir L-1	7/8/2014	·	dates
Salt Fork Lake L-1	7/16/2014	*Aphanizomenon, Cylindrospermopsis	Non-detect
Salt Fork Lake L-2	7/16/2014	*Cylindrospermopsis	Non-detect
Salt Fork Lake L-3	7/16/2014	*Cylindrospermopsis	Non-detect

Algal Toxin Monitoring – Accumulation in Fish Tissue

Because of the uncertainty associated with freshwater algal toxin analysis in fish tissue and the lack of a reliable, U.S. EPA-approved analytical method for microcystin and other algal toxins in fish tissue, the effect of HABs on human health via fish consumption in freshwater systems cannot be definitively determined at this time.

Ohio EPA has conducted multiple surveys looking for microcystin in fish tissue since 2010, primarily in GLSM and more recently in Lake Erie. In general, a large majority of these samples have not had any detections for microcystin, while a few samples have had microcystin detections at relatively low levels.

Early in this investigation, Ohio EPA, ODNR and Ohio Department of Health chose to place a consumption advisory ("do not eat more than one meal per week") on black crappie in GLSM. This "one meal per week" advisory level is equivalent to Ohio's statewide advisory due to mercury, so anglers following the statewide advisory would also be protected from microcystin in GLSM fish. This species represented the worst-case scenario observed in Ohio's waters. Continued investigation has shown a decline in reported microcystin concentrations in GLSM fish, although it is unclear if this is due to a change in toxin concentrations or improvements in the analytical methods.

As the analytical methods and risk assessment continue to evolve, a strong weight-of-evidence is emerging that algal toxins in Ohio fish tissue present a very low risk to consumers of fish, both in Lake Erie and GLSM. Ohio EPA and ODNR are currently planning to continue annual monitoring of fish in these two waterbodies to ensure the safety of fish in Ohio's waters affected by algal blooms.

Use of Satellite Imagery to Evaluate HABs on Lake Erie and Inland Lakes

NOAA continues to provide processed satellite imagery that identifies cyanobacteria and estimates their abundance based on their unique spectral reflectance. NOAA's experimental Lake Erie forecast system,

which predicts cyanobacteria bloom movement based on a hydrodynamic model of the lake, will go operational the summer of 2016, demonstrating NOAA's continued support for this service. The forecasts are included in the Lake Erie HAB bulletins, which are provided to thousands of subscribers in the state, including state agencies, public water systems, beach managers and the general public. More information on the HAB bulletins is available here: http://www.glerl.noaa.gov/res/Centers/HABS/. A new satellite and sensor that will improve bloom detection capabilities and enable detection of HABs on larger inland lakes was successfully launched in 2016. Ohio is one of three states collaborating with NOAA on application of the new satellite data to inland lakes.

Outreach

Ohio EPA continues to coordinate a workshop at Ohio Sea Grant Stone Laboratory in August of each year. This two-day workshop, "Dealing with Cyanobacteria, Algal Toxin and Taste and Odor Compounds," attracts public water supply operators and water managers from Ohio and other states. Instructors include experts from NOAA, OSU and public water supply operators with experience dealing with HABs. Topics covered include ecology of cyanobacteria, limnology concepts, cyanotoxin impacts, historical outbreaks, cyanobacteria relationship with taste and odor compounds, HAB identification, tracking HABs with satellites, using ELISA to evaluate HAB toxins, cyanobacterial cell and toxins removal options, reservoir and source management, sampling and monitoring demonstrations and update on state HAB initiatives.

In 2013, presentations were given at the Non-Point Source Conference, OSU and four other HAB-related speaking engagements, including one at Presque-Isle, Pennsylvania at the request of Pennsylvania Sea Grant. In 2014 presentations were given at OSU, the National Academy of Science, the Warren County Health Department conference and Columbus Bar Association.

Addressing HABs at the Source

In addition to carrying out the HAB strategy and revising the strategy as needed, the State of Ohio continues to seek ways to address the root cause of HABs—excessive nutrients that enter the State's waterways. Ohio EPA, in collaboration with ODNR, ODA, OSU and other third party collaborators, has updated the 2013 Ohio Nutrient Reduction Strategy. The 2015 Addendum describes new initiatives and summarizes progress in the more established programs and activities intended to reduce the loss of nutrient to surface and ground waters. All strategy documents are available on-line at this website http://epa.ohio.gov/dsw/wqs/NutrientReduction.aspx.

C8. New 303(d) Vision Implementation in Ohio

In December 2013, U.S. EPA announced a new "Vision" for the CWA Section 303(d) program to provide an updated framework for implementing the responsibilities under the impaired waters program. U.S. EPA recognized that "... there is not a one-size-fits-all approach to restoring and protecting water resources." Under the new Vision, states will be able to develop tailored strategies to implement the 303(d) program in the context of their water quality goals.

The Vision effort grew out of frustration caused by the 1990s-era litigation concerning the pace at which TMDL analyses were being completed. The resulting consent decrees forced many states to produce great *quantities* of TMDLs that many felt did not contain the necessary *quality* to effectively improve water quality. As the decrees were completed, discussion centered on how to produce better TMDLs that could be implemented to bring about measureable improvements in the quality of the nation's

waters.

Fortunately, Ohio was not burdened by a harsh consent decree and was able to carefully consider how to proceed with TMDLs. Fifteen years ago, Ohio EPA developed an approach to TMDLs that already aligns with the spirit of the Vision. The Ohio TMDL program strives to:

- focus on CWA responsibilities across programs;
- build on the state's investments in monitoring, especially biological monitoring;
- use data efficiently, for multiple programs and purposes;
- restore beneficial uses;
- focus on watersheds: maintain rotating basin structure to enable adaptive management; and
- recognize that water quality is impacted by the actions of many and that it will change over time

Ohio's program grew out of the Agency's water mission, which is rooted in the CWA. Today's new national Vision developed from the same roots, so it should not be surprising that Ohio has been on the Vision path for several years.

Ohio TMDL Program Relative to the Vision Goals

The national Vision contains six goal statements related to prioritization, assessment, protection, alternatives, engagement and integration. While its TMDL program is generally well placed relative to these goals, Ohio expects to continue to improve its program; potentially the biggest opportunities are in the areas of protection and engaging other organizations to help with implementation. The following is a summary of the goals and how Ohio has been addressing each goal to date as detailed in the U.S. EPA document titled, "A Long-Term Vision for Assessment, Restoration and Protection under the Clean Water Act Section 303(d) Program" (U.S. EPA, 2013). https://www.epa.gov/sites/production/files/2015-07/documents/vision_303d_program_dec_2013.pdf.

Prioritization Goal

For the 2016 integrated reporting cycle and beyond, States review, systematically prioritize, and report priority watersheds or waters for restoration and protection in their biennial integrated reports to facilitate State strategic planning for achieving water quality goals.

The intent of the Prioritization Goal is for States to express CWA 303(d) Program priorities in the context of the State's broader, overall water quality goals.

-- U.S. EPA, 2013

Based on the state's established monitoring investment and expertise, Ohio's initial priority (in approximately 2000) was on aquatic life use impairments in streams. This priority led to the development of nutrient, sediment, habitat, dissolved oxygen and related TMDLs. A couple of years later, the agency began to focus on recreation use impairments, which yielded bacteria TMDLs. More recently, work has involved public drinking water use impairments involving nitrate and pesticides TMDLs.

In addition to a focus on restoring uses, other priorities were to begin with headwaters and work downstream. To date, the state has not adopted a geographic priority, choosing instead to work

statewide which helps to maintain work balance among district offices. In cases where other agencies or stakeholders have initiated projects, TMDLs in watersheds has been delayed.

Moving forward, Ohio intends to use the following prioritization framework (**bold** items indicate clarification or change from past practices):

Long Term General Priorities:

- continue to work statewide, using rotating basin scheduling for assessment and listing but on a more limited basis to allow for increased focus on lakes and protecting downstream uses
- sharpen focus on Public Water Supply Use
- Incorporate HAB considerations into priorities (both PDWS use and ultimately Recreation use)
- concentrate recreation TMDLs on **High-Use** recreation waters
- continue to make mercury and legacy/sediment metals low priority TMDLs as other approaches are anticipated to be more effective

Annual Prioritization of Impaired Waters for TMDL Development:

Ohio will continue to use the Priority Point System in Section J2 of the IR. Points are given for presence and severity of Human Health impairment, Recreation Use impairment, Public Water Supply impairment and Aquatic Life Use impairment. Scores by HUC12 range from 1-16.

In addition, the Agency will consider geographic coverage, severity of the impairments represented by the above scores/points for the entire project area and add the following considerations.

- Social Factors (highly used recreational waters, drinking water supply for significant populations, ongoing/sustained involvement of any local groups or government, etc.)
- Value Added (is a TMDL the most efficient way to achieve improved water quality?)
- Is there an approved watershed action plan if so how many implemented projects?
- How much regulatory authority exists over sources?
- Is there an alternative way to improve water quality more quickly than a TMDL? (e.g. immediate implementation of an existing plan or projects, or imposing more stringent permit limits to address a localized problem)
- Are there other factors in play? Examples include:
 - o Pending enforcement for a discharger (possible 4B option)
 - o USACE modeling of reservoir discharge to improve downstream water quality
 - Local or statewide strategy or requirements in place to address a particular issue/pollutant (e.g. new health department rules for HSTS if they are sole/primary source of impairment)

Over time, Ohio will strive to develop a more objective system for weighing the social factors and value added concepts. In each IR, the state plans to provide results of the most recent assessments and prioritization exercise as outlined above; list resulting high priority TMDL projects; and include schedules for those anticipated to be completed in the next two years.

Assessment Goal

By 2020, States identify the extent of healthy and CWA Section 303(d) impaired waters in each State's priority watersheds or waters through site-specific assessment.

The purpose of this Goal is to encourage a comprehensive understanding of the water quality status of at least each State's priority areas.

-- U.S. EPA, 2013

Ohio has maintained a robust biology and chemistry monitoring program for more than 30 years, maintaining consistent protocols and systematically expanding into new water body types. Assessments are based on surveys conducted using a rotating basin approach. The assessments use site-specific data of the highest quality and the status of waters is reported in watershed reports and summarized in biennial IRs that meet the reporting requirements of CWA 305(b) and 303(d). A framework of goals and measures has been in place for several years and reported on biennially in the Ohio IR.

Protection Goal

For the 2016 reporting cycle and beyond, in addition to the traditional TMDL development priorities and schedules for waters in need of restoration, States identify protection planning priorities and approaches along with schedules to help prevent impairments in healthy waters, in a manner consistent with each State's systematic prioritization.

The intent of the Protection Goal is to encourage a more systematic consideration of management actions to prevent impairments in healthy waters (i.e., unimpaired waters) in order to maintain water quality or protect existing uses or high quality waters.

-- U.S. EPA, 2013

Protection of the water resource is built into Ohio's CWA programs in multiple ways. Watershed surveys measure the attainment potential and status for all waters; thus, they identify waters to restore and to protect. Tiered aquatic life uses identify "better than CWA" goals for high-quality streams. About 14 percent of Ohio's streams already have this higher use designation. TMDLs have included protection strategies and "informational TMDLs" to encourage protection of streams currently meeting their designated uses. Ohio also has an active antidegradation process to protect existing uses and plans to update the list of waters afforded higher protection under antidegradation.

Ohio has also issued NPDES permits to protect against water quality impairment and anticipates continuing that approach where warranted. One example is the general construction storm water permits for the Olentangy River and Darby Creek watersheds. Those permits include measures designed to protect the high quality of the streams from development impacts. Other watersheds are being considered for similar actions.

Ohio plans to explore how other types of plans (9 Element Watershed Plans for instance) or regulatory actions could be used more effectively to protect our highest quality waters and/or those that are of high importance for drinking water or recreation.

Alternatives Goal

By 2018, States use alternative approaches, in addition to TMDLs, that incorporate adaptive management and are tailored to specific circumstances where such approaches are better suited to implement priority watershed or water actions that achieve the water quality goals of each state, including identifying and reducing nonpoint sources of pollution.

The purpose of this Goal is to encourage the use of the most effective tool(s) to address water quality protection and restoration efforts.

-- U.S. EPA, 2013

Ohio has been using a number of alternatives to improve water quality. Relying on the biological criteria as the measure for aquatic life attainment means that restoring habitat to build a stream's capacity to process pollutants can be as or more effective than load reduction; Ohio TMDLs have routinely promoted habitat enhancement. After the first few TMDLs recommended dam modifications to enhance capacity, dam modifications were pursued in areas without TMDLs. The state has used CWA Section 319 funds to remove or modify many dams.

In the past, Ohio EPA worked with mining agencies and the Corps to develop a standard alternative for acid mine drainage problems by aligning processes to quantify load reductions, thus meeting the needs of multiple programs with one project. There have also been several instances where NPDES permits have been adjusted to address point source impairments as monitoring identifies them, in advance of completing a TMDL. In other cases, TMDLs have recommended a stressor study to address impairment where the source could not be identified. This follow-up attention increases the chances that the problem may be eliminated or, at a minimum, data will be available for a future TMDL.

Under the new Vision, Ohio EPA also plans to use approaches that are an alternative to a TMDL. These approaches will be designed to address specific impairments caused by pollutants such as phosphorus or perhaps bacteria. Approaches may include developing "9 Element Watershed Plans," revising NPDES permit limits or conditions, funding installation of BMPs, supporting local health departments in implementing new rules for household sewage treatment systems, etc. These approaches will be pursued where there is clear legal authority to do so and circumstances are such that they are likely to result in water quality improvements more efficiently than a TMDL.

Engagement Goal

By 2014, EPA and the States actively engage the public and other stakeholders to improve and protect water quality, as demonstrated by documented, inclusive, transparent, and consistent communication; requesting and sharing feedback on proposed approaches; and enhanced understanding of program objectives.

The purpose of the Engagement Goal is to ensure the CWA 303(d) Program encourages working with stakeholders to educate and facilitate actions that work toward achieving water quality goals.

-- U.S. EPA, 2013

Ohio engages the public and other stakeholders in a number of ways. Ohio EPA maintains an extensive website with information about TMDLs, monitoring and implementation in watersheds across the

state4.

In addition to the outreach in individual CWA programs, the TMDL program developed a standard TMDL project communication plan to engage the public and government and technical stakeholders within a project area. The plan includes a standard set of meetings, demonstrations, articles, new releases, etc., that are tied to TMDL project milestones.

In recent years, the CWA Section 319 program has strived to reach beyond stakeholders with general interest to focus on local decision makers and groups who have the wherewithal to take action "on the ground" to improve water quality. These include local governments and park districts.

The preparation of the IR (containing the 303(d), or impaired waters, list) is an open process. Several years ago an "incubator" section was added to preview changes that were being contemplated for future listings (e.g., adding new beneficial use analyses, revising methodologies or assessment unit types). The section allows for longer-term feedback for public consideration of changes that can have significant impacts. The IR also includes Ohio EPA's projected monitoring schedule; the draft schedule is frequently changed in response to requests for monitoring from watershed groups, communities or others who are committed to improving their water quality in their area. Ohio will strive to complete the IR every two years so that the process remains dynamic and reliable.

Integration Goal

By 2016, EPA and the States identify and coordinate implementation of key point source and nonpoint source control actions that foster effective integration across CWA programs, other statutory programs (e.g., CERCLA, RCRA, SDWA, CAA), and the water quality efforts of other Federal departments and agencies (e.g., Agriculture, Interior, Commerce) to achieve the water quality goals of each state.

The intent of this Goal is to integrate the CWA Section 303(d) Program with other relevant programs that play a role in influencing water quality, in order to collectively and more effectively achieve the water quality goals of States, Tribes, and Territories.

-- U.S. EPA, 2013

As described earlier, program integration is the foundation of Ohio's TMDL work, including both technical and funding programs. Ohio has adopted the Safe Drinking Water Act into the 303(d) listing process and has completed TMDLs for drinking water impairments. Ohio has directed CWA Section 319 funding to park districts and local governments that can directly implement actions to improve water quality by using TMDLs to identify suitable projects. Ohio EPA has also worked with the U.S. Forest Service, U.S. Army Corps of Engineers and state and federal mining agencies to address common water quality goals and to complete TMDLs and TMDL alternatives.

On a practical level, each TMDL project is completed by a team of Ohio EPA staff that represents many aspects of the clean water programs, including drinking water. The team members include staff from various CWA program areas. At a minimum, these program areas include monitoring and assessment; water quality modeling; NPDES permits; enforcement; water quality standards; and TMDL. Staff from the Agency's Public Water Supply program and Public Interest Center is also part of each team. Ohio EPA

⁴ http://epa.ohio.gov/dsw/tmdl/index.aspx

district offices and central office both contribute to the effort. On some projects, local representatives such as active watershed group leaders or Soil and Water Conservation District staff are involved during the study plan phase and throughout the project.

For most projects external input is sought for developing the implementation portion of the TMDL. Most commonly, Soil and Water Conservation Districts and watershed groups are consulted, but permittees or other entities may also be asked for input in the development stage of the implementation plan, depending upon the issues in the watershed. While there is always room for improvement, Ohio EPA does not propose significant changes in the integration aspect over the next few years in terms of our internal coordination. But it should be noted that since the Supreme Court of Ohio determined that TMDLs are subject to the administrative rule making procedures⁵, it is anticipated that the future process in Ohio for developing and finalizing TMDLs will include more opportunities for external stakeholders to participate, as well as provide an avenue for effected parties to appeal the final decision.

⁵ On March 24, 2015, the Supreme Court of Ohio determined that "A TMDL established by Ohio EPA pursuant to the Clean Water Act is a rule that is subject to the requirements of R.C. Chapter 119, the Ohio Administrative Procedure Act. Ohio EPA must follow the rulemaking procedure in R. C. Chapter 119 before submitting a TMDL to U.S.EPA for its approval, and before the TMDL may be implemented in an NPDES permit."

Framework for Reporting and Evaluation

Case: 3:17-cv-01514-JGC Doc #: 1-12 Filed: 07/18/17 93 of 601. PageID #: 1090

This section describes the framework and basic elements for evaluating and reporting the water quality information in this report.

The 2016 Integrated Report (IR) continues Ohio's evolution to a fully-formed watershed basis for reporting on water quality conditions. For the past 20 years Ohio has maintained strong linkages between Clean Water Act (CWA) Section 305(b) reporting and Section 303(d) listing. Under the title *Water Resource Inventories*, Ohio prepared CWA Section 305(b) reports every two years since 1988 using a biologically based assessment methodology¹. Subsequently, CWA Section 303(d) lists were compiled using the output of CWA Section 305(b) reporting in 1992, 1994, 1996 and 1998. In 2002, the first IR was produced, addressing the needs of both reporting requirements.

Reporting on Ohio's water resources continues to develop, including more data types and more refined methodologies. The basic framework for this report is built on four beneficial uses, as follows:

- Aquatic Life: Analysis of the condition of aquatic life was the long-standing focus of reporting on water quality in Ohio and continues to provide a strong foundation. The 2016 methodology is unchanged from what was used in the 2014 IR. Additionally, as in the 2012 and 2014 IRs, a methodology for assessing the aquatic life condition of inland lakes is previewed for possible inclusion in the 2018 or 2020 report provided necessary rule revisions to the Ohio Water Quality Standards are promulgated.
- 2. <u>Recreation</u>: A methodology for using bacteria data to assess recreation suitability was developed for the 2002 report and refined in 2004, remaining essentially the same for 2006 and 2008. In 2010, the recreation use analysis changed significantly to a new indicator, a new water quality standard, and a data grouping procedure similar to that used for aquatic life. The methodology has not changed for the 2016 report.
- 3. <u>Human Health</u>: A methodology for comparing fish tissue contaminant data to human health criteria via fish consumption advisories was included in the 2004 report. That methodology has been refined in each subsequent report to align more directly with the human health water quality criteria. The methodology was changed in the 2010 report to be consistent with the methodology described in U.S. EPA's 2009 guidance for implementing the methylmercury water quality criterion. The methodology has not changed for the 2016 report.
- 4. Public Drinking Water: The assessment methodology for the public drinking water supply (PDWS) beneficial use was first presented in the 2006 report. Updates to the methodology have been presented in subsequent reports. For the 2014 report, it was revised to include a new core indicator based on algae and associated cyanotoxins, and assessment units listed as impaired for algae. The methodology has not changed for the 2016 report.

The methodology for assessing support of each beneficial use is described in more detail in Sections E through H.

¹ In 1990, the linkage of fish and macroinvertebrate community index scores and attainment of aquatic life use designations was established in Ohio's Water Quality Standards (OAC 3745-1).

D1. Assessment Units

The 2016 IR continues the watershed orientation outlined in previous reports; the assessment units have not changed significantly from the 2010 report. Throughout this report, references are made to large rivers and watersheds as assessment units defined for 303(d) listing purposes. Data from individual sampling locations in an assessment unit are accumulated and analyzed; summary information and statewide statistics are provided in this report. The three types of assessment units (AUs) are:

- 1. Watershed Assessment Units (WAUs) 1,538 watersheds that align with the 12-digit hydrologic unit code (HUC) system. Ohio HUC numbers are lowest in the northwest corner of the state, proceeding approximately clockwise around the state. The first two digits of Ohio numbers are either 04 (draining to Lake Erie) or 05 (draining to the Ohio River).
- 2. Large River Assessment Units (LRAUs) 38 segments in the 23 rivers that drain more than 500 square miles; the length of each river included is from the mouth of each river upstream to the point where the drainage area reaches approximately 500 square miles.
- 3. Lake Erie Assessment Units (LEAUs) for three shoreline areas of the lake: western (Ohio/Michigan state line to eastern terminus of Sandusky Bay opening to Lake Erie); central (eastern terminus of Sandusky Bay opening to Lake Erie to Ohio/Pennsylvania state line); and Lake Erie islands (including South Bass Island, Middle Bass Island, North Bass Island, Kelleys Island, West Sister Island and other small islands) extending 100 meters from the shore. These assessment units also include Public Drinking Water Supply intake zones (500-yard radius around intakes) associated with the nearest shoreline unit even if they are greater than 100 meters from the shore.

Ohio River assessment units have been defined by the Ohio River Valley Water Sanitation Commission (ORSANCO). See Section D2 for additional discussion of ORSANCO's work.

It is important to remember that the information presented here is a summary. All of the underlying data observations are available and can be used for more detailed analysis of water resource conditions on a more localized, in-depth scale. Much of the information is available in watershed reports available at http://www.epa.ohio.gov/dsw/document_index/psdindx.aspx. Total Maximum Daily Load (TMDL) reports, available at http://www.epa.ohio.gov/dsw/tmdl/index.aspx, are another source of more indepth analyses. Water chemistry data collected by Ohio EPA's Division of Surface Water (DSW) is regularly reviewed and uploaded to the national STORET Data Warehouse. Approved data collected from 2005 to present can be queried and downloaded from STORET via the Water Quality Portal at http://www.waterqualitydata.us/. Ohio EPA data can be found under the organization ID "210HIO_WQX". Biological data is available from Ohio EPA upon request but is not currently available through the Water Quality Portal or STORET.

Ohio's large rivers, defined for this report as draining greater than 500 square miles, are illustrated in Figure D-1. Ohio's watershed units are shown in Figure D-2.

Figure D-1. Ohio's large rivers (rivers with drainages greater than 500 mi²) and their watersheds. *Note: Bolded river names indicate the primary mainstem of that drainage basin.*

Figure D-2. Ohio's 12-digit WAUs (gray lines) and 8-digit hydrologic units (heavy black lines).

D2. Evaluation of the Ohio River

Since 1948, the Ohio River Valley Water Sanitation Commission (ORSANCO) and its member states have cooperated to improve water quality in the Ohio River Basin so that the river and its tributaries can be used for drinking water, industrial supplies and recreational purposes; and can support healthy and diverse aquatic communities. ORSANCO operates monitoring programs to check for pollutants and toxins that may interfere with specific uses of the river and conducts special studies to address emerging water quality issues. ORSANCO was established on June 30, 1948, to control and abate pollution in the Ohio River Basin. ORSANCO is an interstate commission representing eight states and the federal government. Member states include Illinois, Indiana, Kentucky, New York, Ohio, Pennsylvania, Virginia and West Virginia. ORSANCO operates programs to improve water quality in the Ohio River and its tributaries including: setting wastewater discharge standards; performing biological assessments; monitoring for the chemical and physical properties of the waterways; and conducting special surveys and studies. ORSANCO also coordinates emergency response activities for spills or accidental discharges to the river and promotes public participation in the programs such as the Ohio River Sweep, RiverWatchers Volunteer Monitoring Program and Friends of the Ohio.

As a member of the Commission, the state of Ohio supports ORSANCO activities, including monitoring of the Ohio River mainstem, by providing funding based on state population and miles of Ohio River shoreline. As such, monitoring activities on the Ohio River are coordinated and conducted by ORSANCO staff or its contractors. More information about ORSANCO and the Ohio River monitoring activities conducted through that organization can be found online at http://www.orsanco.org.

Ohio EPA participates in an ORSANCO workgroup to promote consistency in 305(b) reporting and 303(d) listing. The workgroup discussed and agreed upon methods to evaluate attainment/non-attainment of aquatic life, recreation and public water supply uses, as well as impairments based on sport fish consumption advisories. ORSANCO prepares the Section 305(b) report for the Ohio River and has indicated the impaired beneficial uses and segments of the Ohio River. Ohio EPA defers to the ORSANCO analysis and the list of impaired Ohio River segments found in 2014 Biennial Assessment of Ohio River Water Quality Conditions (ORSANCO 2014). ORSANCO plans to complete a biennial assessment in 2016, but the document is not expected to be available by the time Ohio's 2016 IR will be available for public review. When completed, the 2016 biennial assessment will be available at: http://orsanco.org/biennial-assessment-of-ohio-river-water-quality-conditions-305b.

D3. Evaluation of Lake Erie

Lake Erie is bordered by four states and one Canadian province. As such, it has federal oversight by two sovereign nations. Unlike most other waters in Ohio, Lake Erie has a more complicated governance structure with a binational agreement (GLWQA) between the U.S. and Canada providing a framework to identify binational priorities and implement actions that improve water quality. For comparison, assessment and reporting on one of Ohio's other multi-state waters, the Ohio River, is conducted by ORSANCO, which, as stated above, is an interstate commission representing eight states and the federal government.

Ohio's assessment and impairment designation for Lake Erie has been the focus of considerable discussion between Ohio EPA, U.S. EPA and local stakeholders. In Ohio's 2014 Integrated Water Quality Report *Section I: Considerations for Future Lists*, Ohio proposed a new approach for Lake Erie with new

assessment units and methodology for the nearshore and open waters. Ohio EPA initially planned to adopt the new assessment units and methodology during a later IR cycle, anticipating that the GLWQA Annex 4 efforts would produce nutrient concentration targets or criteria for the open waters.

The GLWQA Annex 4 efforts so far have resulted in load reductions targets rather than in-lake nutrient concentration targets or criteria. For this and other reasons outlined in Section J3, Ohio does not intend to pursue development of the open water assessment units and methods at this time. Ohio EPA believes that assessment and listing of the open waters under the CWA should be led by U.S. EPA in consultation with the states and Ohio is willing to assist its federal partners with the development of appropriate monitoring and assessment protocols for the open waters. Federal leadership on the open water assessments will also facilitate coordination with the ongoing GLWQA Annex 4 efforts (U.S. EPA and Environmental Canada are federal co-leads). In the meantime, Ohio is actively working towards the nutrient reduction goals for Lake Erie recommended by the Annex 4 subcommittee (see Section J3 for more information).

To be clear, the three current Lake Erie shoreline units have been assessed and impairment determinations made for the aquatic life use, recreational use, and human health (fish contaminants) use for over 10 years. In the 2014 IR, the Western Basin Shoreline Unit was listed as impaired for all four beneficial uses, including the public drinking water supply beneficial use for the first time. Public drinking water supply intakes that are located in Lake Erie beyond 100 meters from the shore were associated with the nearest shoreline assessment units. An algae indicator assessment methodology was implemented for the first time in the 2014 report, based on the state drinking water thresholds for microcystins, saxitoxin, anatoxin-a and cylindrospermopsin. This association and application for assessment and listing has been clarified in response letters to U.S. EPA in 2015 and in this report. These impairment determinations were made based on numeric targets or standards and objective assessment methods for each use designation (see Sections E through H for more information about how impairment is determined for each use) in line with how assessments for large river and watershed units have been conducted for the last several report cycles.

For this 2016 IR, Ohio has continued to use the three Lake Erie shoreline assessment units with all four beneficial uses assessed and all Lake Erie public drinking water intakes associated with one of the three units, as shown in Figure D-3. The shoreline unit extends 100 meters from the actual shore. The 303(d) Prioritized List of Impaired Waters (Table L4) includes all three assessment units and shows that all three are now listed as impaired for aquatic life use, public drinking water use and human health (fish tissue). The western basin shoreline and central basin shoreline are also listed as impaired for recreation use by bacteria (e. coll).

D4. Ohio's Water Quality Standards Use Designations

Beneficial use designations describe existing or potential uses of water bodies. They take into consideration the use and value of water for public water supplies, protection and propagation of aquatic life, recreation in and on the water, agricultural, industrial and other purposes. Ohio EPA assigns beneficial use designations to water bodies in the state. There may be more than one use designation assigned to a water body. Examples of beneficial use designations include: public water supply, primary contact recreation, and numerous sub-categories of aquatic life uses. Table D-1 lists all of Ohio's water quality standards (WQS) designated uses and outlines how the use was evaluated for the Ohio 2016 IR.

Figure D-3. Ohio's Lake Erie assessment units – western basin, islands and central basin shoreline with associated Public Water Supply intake zones.

Table D-1. Ohio water quality standards in the 2016 IR.

Beneficial Use Category	Key Attributes ²	Evaluation status in the 2016 IR			
Categories for the protection of aquatic life					
Coldwater habitat (CWH)	native cold water or cool water species; put-and-take trout stocking	Assessed on case by case basis			
Seasonal salmonid habitat (SSH)	supports lake run steelhead trout fisheries	No direct assessment, streams assessed as EWH or WWH			
Exceptional warmwater habitat (EWH)	unique and diverse assemblage of fish and invertebrates	64 percent of the WAUs and 98 percent of the LRAUs fully			
Warmwater habitat (WWH)	typical assemblages of fish and invertebrates	assessed using direct comparisons of fish and macroinvertebrate			
Modified warmwater habitat	tolerant assemblages of fish and macro- invertebrates; irretrievable condition precludes WWH	community index scores to the biocriteria in Ohio's WQS; sources and causes of impairment were assessed using biological indicators and water chemistry data.			
Limited resource water	fish and macroinvertebrates severely limited by physical habitat or other irretrievable condition	Assessed on case by case basis			
Categories for the protection of r	ecreational activities				
Bathing Waters	Lake Erie (entire lake); for inland waters, bathing beach with lifeguard or bathhouse facility	Lake Erie public beaches fully evaluated; nine inland lakes evaluated			
Primary Contact Recreation (PCR)	waters suitable for one or more full- body contact recreation activity such as wading and swimming; three classes are recognized, distinguished by relative potential frequency of use	45 percent of the WAUs, 45 percent of the LRAUs and 100 percent of beaches in LEAUs assessed using applicable PCR geometric mean <i>E. coli</i> criteria			
Secondary Contact Recreation (SCR)	waters rarely used for recreation because of limited access; typically located in remote areas and of very shallow depth	Assessed as part of the WAU using applicable SCR geometric mean <i>E. coli</i> criteria			
Categories for the protection of w	rater supplies				
Public Water Supply	waters within 500 yards of all public water supply surface water intakes, publically owned lakes, waters used as emergency supplies	Sufficient data were available to assess 57 percent of the 123 AUs with PDWS use; assessed using chemical water quality data; only waters with active intakes were assessed			
Agricultural Water Supply	water used, or potentially used, for livestock watering and/or irrigation	Not assessed			
Industrial Water Supply	water used for industrial purposes	Not assessed			

² Reasons for which a water body would be designated in the category.

D5. Sources of Existing and Readily Available Data

For two decades Ohio EPA has placed a high priority on collecting data to accurately measure the quality of Ohio's rivers and streams. Therefore, the Agency has a great deal of information and data to draw upon for the IR. The available data sets from Ohio EPA and external sources, including efforts used to obtain additional data, are also discussed below. The 2008 IR marked the first time that Ohio's credible data law was fully implemented in generating external data for consideration.

The "credible data law," enacted in 2003 (ORC 6111.50 to 6111.56), requires that the director of Ohio EPA adopt rules which would, among other things, do the following:

- establish a water quality monitoring program for the purpose of collecting credible data under the act; require qualified data collectors to follow plans pertaining to data collection; and require the submission of a certification that the data were collected in accordance with such a plan; and
- establish and maintain a computerized database or databases of all credible data in the director's possession and require each state agency in possession of surface water quality data to submit that data to the director.

Ohio EPA adopted rules in 2006, revised in 2011, to establish criteria for three levels of credible data for surface water quality monitoring and assessment and to establish the necessary training and experience for persons to submit credible data. Apart from a few exceptions, people collecting data and submitting it to Ohio EPA for consideration as credible data must have status as a qualified data collector (QDC). Only Level 3 data can be used for decisions about beneficial use assignment and attainment; water quality standards; listing and delisting (303(d) list); and TMDL calculations.

Ohio EPA solicited data from all Level 3 QDCs for the 2016 IR. The letter requesting data and the web site containing information about how to submit data are included in Section D5.1. Table D-2 summarizes the WQS uses evaluated in the 2016 IR, the basic types of data used, the period of record considered, the sources of data and the minimum amount of data needed to evaluate a water body. Specific methodologies used to assess attainment of the standards are described in more detail in Sections E through H.

Table D-3 summarizes the data Ohio EPA used in the 2016 IR. Ohio EPA's 2016 IR uses fish contaminant data to determine impairment using the human health based water quality criteria. Fish consumption advisories (FCAs) were not used in determining impairment status. However, the public should use the FCAs in determining the safety of consuming Ohio's sport fish.

The evaluation of bacteria, biological and water quality survey data was not changed from the approach used in the 2010 IR. Data collected by Ohio EPA and Level 3 QDCs were evaluated. The following QDCs submitted data or the data were available from readily obtained reports:

- Ohio Department of Natural Resources
- U.S. Geological Survey
- Northeast Ohio Regional Sewer District
- Midwest Biodiversity Institute/Center for Applied Bioassessment and Biocriteria

- Heidelberg College
- The Ohio State University
- Ohio Department of Health
- Cuyahoga County Board of Health
- EnviroScience, Inc.
- EA Science and Technology, Inc.
- Cleveland Metroparks

Table D-2. Data types used in the 2016 IR.

WQS Uses and Criteria Evaluated (basic rationale ³)	Type of Data Time Period	Source(s) of Data	Minimum Data Requirement
Human health, single route exposure via food chain accumulation and eating sport fish (criteria apply to all waters of the State)	Fish Tissue Contaminant Data 2005 to 2014	Fish Tissue Contaminant Database	Data collected within past 10 years. Two samples, each from trophic levels 3 and 4 in each WAU or inland lake.
Recreation uses and subclasses - evaluation based on a comparison of <i>E. coli</i> levels to applicable geometric mean <i>E. coli</i> criteria in the WQS. Lake Erie shoreline evaluated on the basis of frequency of advisories posted at beaches	E. coli counts 2011 to 2015 (May through October only)	Ohio Dept of Health Cuyahoga County Health Department Northeast Ohio Regional Sewer District (NEORSD)	Bathing Waters – One or more geometric mean <i>E. coli</i> values (inland lakes; <i>E. coli</i> data from one or more beaches (Lake Erie shoreline AUs); minimum of one geometric mean <i>E. coli</i> concentration per WAU or one site every ~5 to 7 river miles for LRAUs
Aquatic life (specific subcategories), fish and macroinvertebrate community index scores compared to biocriteria in WQS ⁴	Watershed scale biological and water quality surveys & other more targeted monitoring 2003 to 2014	ODNR U.S. Geological Survey NEORSD Midwest Biodiversity Institute Heidelberg College Ohio State University EnviroScience, Inc.	Fish and/or macroinvertebrate samples collected using methods cited in WQS ⁵ . Generally, 2 to 3 locations sampled per WAU (12-digit HUC).
Public drinking water supply (criteria apply within 500 yards of active drinking water intakes, all publically owned lakes, and all emergency water supplies)	Chemical water quality data 2010 to 2015	SDWIS (PWS compliance database) Syngenta Crop Protection, Inc. (Atrazine Monitoring Program) ⁶	Data collected within past five years. Minimum of 10 samples with a few exceptions (noted in Section H).

³ Additional explanation is provided in the text of Section D2.

⁴ OAC 3745-1-07(A)(6) and Table 7-15

⁵ OAC 3745-1-03(A)(5)

⁶ These data were collected as part of an intensive monitoring program at community water systems required by the January 2003 Atrazine Interim Reregistration Eligibility Decision and subsequent Memorandum of Agreement between U.S. EPA and the atrazine registrants (including Syngenta Crop Protection, Inc.).

Table D-3. Description of data used in the 2016 IR from sources other than Ohio EPA.

Entity	Dates data were collected	Data description	Basis of qualification ⁷		
Data Collected Before Credible Data Law (March 24, 2006)					
Ohio Donartment of Natural	1997 – 2005	Fish tissue			
Ohio Department of Natural Resources	2003 – 2005	Biology (fish only) Physical habitat			
U.S. Geological Survey	2003	Biology (macroinvertebrates only)			
Northeast Ohio Regional Sewer District	2005	Fish tissue			
Midwest Biodiversity		Biology			
Institute/Center for Applied Bio-assessment and	2003 – 2004	Physical habitat			
Biocriteria		Chemistry	1		
Heidelberg College	2004	Biology (macroinvertebrates only)			
and the grant gran	Jan 2002 – Feb 2006	Chemistry			
Data Collected After Credible L	Data Law (March 24, 200	06)			
NPDES permittees	2011 – 2015 (May – Oct only)	Bacteria	Data credible – submittal pursuant to permit		
Ohio Department of Health (ODH)	2011 – 2015 (May – Oct only)	Bacteria	State agency		
Cuyahoga County Health Department	2011 – 2015 (May – Oct only)	Bacteria	Level 3 qualified data collector (under ODH's study plan)		
Northeast Ohio Regional	2011 – 2015 (May – Oct only)	Bacteria	Level 3 qualified data		
Sewer District	Jul 2006 – Oct 2014	Physical habitat	collector		
	2008	Fish tissue			
Ohio Department of Natural	Apr 2006 – Nov 2014	Fish tissue	State agency/Level 3		
Resources	Sep 2006 – Sep	Biology (fish only)	qualified data collector		
	2014	Physical habitat			
PWS compliance database (permittees)	Jan 2010 – Dec 2015	Chemistry	Data credible – submittal pursuant to permit		
Syngenta Corp Protection, Inc.	Jan 2010 – Dec 2015	Chemistry	See footnote ⁸		

⁷ Level 3 qualified data collector requirements are described in OAC Rule 3745-4-03(A)(4). Included above are qualified data collectors Ohio EPA has approved for stream habitat assessment, fish community biology, benthic macroinvertebrate biology and/or chemical water quality assessment.

⁸ These data were collected as part of an intensive monitoring program at community water systems required by the Jan 2003 Atrazine Interim Reregistration Eligibility Decision and subsequent Memorandum of Agreement between U.S. EPA and the atrazine registrants (including Syngenta Crop Protection, Inc.).

Entity	Dates data were collected	Data description	Basis of qualification ⁷
The Ohio State University	May – Oct 2006	Biology (macroinvertebrates only)	Level 3 qualified data collector

Environmental Quality	2013	Biology	collector
_		(macroinvertebrates only)	

D6. Public Involvement in Compiling Ohio's Section 303(d) List of Impaired Waters

The public was involved in various ways in the development of the 2016 IR. Several means of public communication are discussed below.

Ohio EPA convened an advisory group that included representatives from the regulated community (e.g., industries, municipalities), environmental groups, consultants, citizens, state and federal agencies, farm organizations and development interests. The group, which included about 80 active participants, met from late 1998 to June 2000. One subgroup addressed listing issues. Their conclusions were as follows:

- monitoring and data quality are essential
- use outside data of highest quality
- endorse priorities of 1998 list
- increase attention to human health issues
- quantify "cost of inaction"
- more monitoring is needed
- data should be accessible and geographically referenced
- increased public involvement is needed
- current funding and resources are inadequate

The cost associated with implementing the advisory group's listing recommendations was \$3.2 million annually; the cost for implementing all advisory group recommendations was \$9.7 million annually. Ohio EPA used these estimates to seek additional monies, but ultimately was unsuccessful in competing with other state funding priorities. Ohio EPA has incorporated the "low cost" recommendations (the

first four listed above) and it continues to seek ways to address all of the group's recommendations.

Much of the data used in this report have been presented to the public in meetings and publications concerning individual watersheds. Data and assessments have also been available in previous 305(b), 303(d), and IRs. All of this information can be accessed from the following Internet web site: http://www.epa.ohio.gov/dsw/formspubs.aspx.

The draft 2016 303(d) list, contained in the draft 2016 IR, will be also available for public review and comment prior to submitting the final list and report to U.S. EPA.

D6.1 Solicitation for External Water Quality Data, 2016 IR Project (June 2, 2015)

A memorandum soliciting level 3 qualified data was mailed in June 2015 to all Level 3 qualified data collectors. The memorandum is displayed below.

Date June 2, 2015

To Interested Parties: Stream Monitoring Personnel

Re Solicitation of Water Quality Data, 2016 Integrated Report (No action is required on your part - submission of data is voluntary)

Ohio EPA is asking for chemical, biological and/or physical data you may wish to submit for consideration as the Agency prepares its 2016 Integrated Report. Both the state and federal governments have an interest in utilizing all available data to make informed decisions about managing Ohio's aquatic resources. Ohio EPA is only able to use data from a limited number of external sources, including Level 3 certified data collectors and NPDES discharge permit holders².

At this time, the Ohio EPA Division of Surface Water (DSW) is soliciting readily available data for use in the 2016 Integrated Report. The report, due to U.S. EPA on April 1, 2016, fulfills the State's reporting obligations under Sections 305(b) and 303(d) of the Clean Water Act. Information is available

at http://www.epa.ohio.gov/dsw/tmdl/OhioIntegratedReport.aspx.

Credible Data Law

In 2003 a new law was enacted in Ohio dealing with sources of data external to Ohio EPA. The "credible data law," as it is known (ORC 6111.50 to 6111.56), requires that the director of Ohio EPA adopt rules which would, among other things, do the following:

- establish a water quality monitoring program for the purpose of collecting credible data under the act, require qualified data collectors to follow plans pertaining to data collection, and require the submission of a certification that the data were collected in accordance with such a plan; and
- establish and maintain a computerized database or databases of all credible data in the director's possession, and require each state agency in possession of surface water quality data to submit them to the director.

The director has adopted rules (OAC 3745-4-01 through 06), effective March 2006, that delineate these requirements.

In addition, the law explicitly established that external data found compliant with the specifications for "Level 3 credible data," which generally means data from a Level 3 Qualified Data Collector, can be used for certain regulatory and reporting purposes, such as the Section 303(d) list.

² It is unnecessary to resubmit data that have already been submitted to the Division of Surface Water.

According to the Ohio EPA administrative rules, you may meet the qualifications of a "Level 3 Qualified Data Collector" in one or more areas of water quality data. Therefore, in pursuit of all readily available data for use in the state's reporting documents, the Agency is requesting your voluntary participation by submitting any recent water quality data that you have on Ohio's waters (e.g., lakes, rivers, streams and wetlands) that you are qualified to collect. Data submission deadlines are dependent on the type of data:

- Biological, physical, and chemical = July 15, 2015
- Bacteria = September 15, 2015

More information about the specific types of data being requested by Ohio EPA, and how to submit such data, can be found at: http://www.epa.ohio.gov/dsw/tmdl/2016IntReport/2016CallForData.aspx

D6.1.1 Web Page with Instructions for Submitting Level 3 Credible Data

For organizations interested in submitting data to Ohio EPA, a web page was established with instructions on what qualified data to be submitted and how to do so. The web site content is displayed below.

2016 Integrated Water Quality Monitoring and Assessment Report - Call for Level 3 Credible Data

Information about submitting Level 3 credible data to Ohio EPA is organized as outlined below. More information about the Integrated Report is on the <u>Ohio Integrated Water Quality Monitoring</u> and Assessment Report page.

- What kind of data does Ohio EPA want?
 - o Microbiological Data
 - o Biological and Physical Data
 - o Chemical Water Quality Data
- Do I have Level 3 data?
- Have I already given Ohio EPA my data?
- What will be needed in addition to data?

What kind of data does Ohio EPA want?

Ohio EPA is asking for biological, physical and/or chemical data you may wish to submit for consideration as the Agency prepares its 2016 Integrated Report. Both the state and federal governments have an interest in utilizing all available data to make informed decisions about managing Ohio's aquatic resources. Ohio EPA is soliciting data primarily from NPDES major permit holders, Level 3 Qualified Data Collectors and others that may be in possession of Level 3 credible data. The data can be of various types (bacteria, biological, physical, and chemical water quality

data) and must have been collected during the following time frame:

- Bacteria = 2013 2015 (recreation season)
- Biological, physical, and chemical = 2013 2014

Microbiological Data

- Ohio EPA measures recreation use attainment by comparing the level of indicator bacteria
 present in ambient water samples against the bacteria criteria contained in <u>rule 3745-1-07 of</u>
 <u>Ohio's water quality standards</u>. These indicator bacteria serve as predictors for the presence of
 enteric pathogens in the water that can cause a variety of illnesses. The type of indicator
 bacteria that Ohio EPA is utilizing in the 2016 Integrated Report is E. coli.
- Data collected by NPDES discharge permit holders at ambient stream sites upstream and downstream of discharge locations and reported in discharge monitoring reports (DMRs) will be extracted from the SWIMS database. It is unnecessary to resubmit data already submitted into SWIMS. However, if bacteria data were collected at additional ambient stations and not reported through SWIMS, permit holders may voluntarily submit this data to the Agency. Data must have been collected between May 1, 2013 and September 15, 2015 and must meet the basic terms of acceptability found in the requirements listed below.

Biological and Physical Data

- Ohio EPA measures aquatic life use attainment in Ohio streams and rivers by comparing
 indices generated from fish and aquatic macroinvertebrate data against the biological criteria
 contained in Ohio's water quality standards, <u>OAC 3745-1-07, Table 7-15</u>. Field collection and
 data analysis methodologies for fish and macroinvertebrate community assessments are
 strictly adhered to and must follow procedures as outlined in the <u>Ohio EPA biological criteria</u>
 manuals.
- Chemical water quality data collected in conjunction with biological data is of interest to Ohio EPA. Data should follow the parameters discussed below.

Chemical Water Quality Data

Ohio EPA primarily uses sampling methods described in the "Manual of Ohio EPA Surveillance
 <u>Methods and Quality Assurance Practices, 2009 Revision"</u>. Sample collection and analysis
 method references are listed in <u>paragraph (C) of OAC 3745-4-06</u>. Ohio EPA is interested in
 other chemical water quality data collected and analyzed by these methods or others of similar
 quality control/quality assurance rigor.

Do I have Level 3 data?

In 2003, a new law was enacted in Ohio dealing with external sources of data. The "credible data law," as it is known (ORC 6111.50 to 6111.56), requires the director of Ohio EPA to adopt rules that would, among other things:

- establish a water quality monitoring program for the purpose of collecting credible data under the act, require qualified data collectors to follow plans pertaining to data collection, and require the submission of a certification that the data were collected in accordance with such a plan; and
- establish and maintain a computerized database or databases of all credible data in the director's possession, and require each state agency in possession of surface water quality data to submit them to the director.

The director has adopted rules (<u>OAC 3745-4-01 to 06</u>), effective March 2006, to accomplish these requirements.

In addition, the law explicitly established that external data found compliant with the specifications for "Level 3 credible data," which generally means data from a Level 3 Qualified Data Collector, can be used for certain regulatory and reporting purposes, such as the Section 303(d) list of Ohio's impaired waters.

Have I already given Ohio EPA my data?

External data Ohio EPA has received and may use for 305(b)/303(d) reporting:

What will be needed in addition to data?

Specific guidelines for submission of data are listed below. While these guidelines correspond to the regulations regarding credible data, they are not verbatim. To see the regulations, please go to OAC 3745-4-06.

Microbiological Data Requirements

An individual or organization who submits bacteria data to Ohio EPA for consideration in the 2016 Integrated Report shall attest to the validity of the data and adhere to the data quality specification listed here. The submission of data must cover the following:

 Sampling and Test Methods, QA/QC Specifications: Sampling must be conducted in a manner consistent with procedures contained in Standard Methods for the Examination of Water and Wastewater or the <u>"Manual of Ohio EPA Surveillance Methods and Quality Assurance</u> <u>Practices, 2009"</u>.

Analytical testing must be conducted in accordance with U.S. EPA approved methods under 40 <u>CFR 136.3</u>. Acceptable references for methods for qualified data collectors are given in <u>paragraph (C) of OAC 3745-4-06</u> and include Ohio EPA references, U.S. EPA references, and Standard Methods. Data submissions must include a description of the Quality Assurance/Quality Control (QA/QC) plans under which the bacteria sample analysis occurred. This should address topics such as sample handling and preservation, sample holding time, chain of custody, precision, accuracy, etc.

• Description of Sampling Program: A brief description of the purpose of data collection and the sampling design considerations should be provided. Were specific sources of potential contamination under investigation? Were samples collected at fixed station locations? How

² These data were collected as part of an intensive monitoring program at community water systems required by the Jan 2003 Atrazine Interim Reregistration Eligibility Decision and subsequent Memorandum of Agreement between U.S. EPA and the atrazine registrants (including Syngenta Crop Production, Inc.).

often and under what kinds of environmental conditions were samples collected? Have the results been published in a report or the scientific literature?

- Minimum Data Submission: Ohio EPA is requesting only bacteria data (E. coli) collected during the recreation season (May 1st to October 31st) for 2013-2014 and (May 1st to September 15th) for 2015. The following information must be included in the data submission in an electronic spreadsheet or database format:
 - o Sample collection date
 - Sample collection method (with reference)
 - o Sample site location including water body name, county, river mile (if known), latitude/longitude (decimal degrees or degrees, minutes, and seconds)
 - o E. coli count
 - Identification of units associated with bacteria counts
 - o Any applicable data qualifiers (as received from the lab, if applicable)
 - o Contact name, address, telephone number, and e-mail address of the person submitting the data set
 - o Identification of the laboratory performing the sample analysis

Biological, Chemical and Physical Data Requirements

An individual or organization who submits biological, chemical and/or physical data to Ohio EPA for consideration in the 2016 Integrated Report shall attest to the validity of the data and adhere to the data quality specification listed here. The submission of data must cover the following:

- Analytical and sampling procedures (examples):
 - o Manual of Ohio EPA Surveillance Methods and Quality Assurance Practices, 2009
 - Habitat and biology sampling manuals
 - o Only data that are consistent with these guidelines can be considered Level 3 data.
- Description of Sampling Program: A brief description of the purpose of data collection and the sampling design considerations should be provided. Were specific sources of potential contamination under investigation? Were samples collected at fixed station locations? How often and under what kinds of environmental conditions were samples collected? Have the results been published in a report or the scientific literature?
 - o If the data have been or will be submitted as part of the Credible Data Program and there is an approved project study plan, this requirement is potentially waived, pending a successful data review that confirms study plan was adhered to as written.
- Minimum Data Submission: Ohio EPA is requesting biological, chemical and physical data collected from 2013-2014. The following information must be included in the data submission in an electronic spreadsheet or database format:
 - o Sample collection date
 - Sample collection method (with reference)

- Sample site location including waterbody name, county, river mile (if known), latitude/longitude (decimal degrees or degrees, minutes and seconds)
- o Type of data collected (fish, macroinvertebrate, chemical and physical parameters)
- Analytical and collection methodologies used (include references)
- o Any applicable data qualifiers (as received from the lab, if applicable)
- o Contact name, address, telephone number, and e-mail address of the person submitting the data set
- o Identification of the laboratory performing the sample analysis (if applicable)
- Weather conditions, flow, and precipitation (all optional)

How do I send the data?

If you have bacteria data collected from surface waters in Ohio, then Ohio EPA would be interested in discussing its possible use in the Integrated Report. Contact Chris Skalski at (614) 644-2144 or chris.skalski@epa.ohio.gov before preparing and submitting any information. The Agency's capacity to accept and utilize the data in preparation of the Integrated Report is dependent upon a variety of factors and the use of all data brought to our attention may not be possible. Data must have been collected after May 1, 2006 and must meet the basic acceptability specifications listed above. Data must be provided in electronic format such as STORET, Excel or Access.

Ohio EPA already has data from some credible data collectors, as listed in the table above. Additional data may be available and Ohio EPA is soliciting these data. If you have biological, chemical or physical data collected from surface waters in Ohio, then Ohio EPA would be interested in discussing its possible use in the Integrated Report. Contact Jeff DeShon at (614) 836-8780 or jeffrey.deshon@epa.ohio.gov before preparing and submitting any information. The Agency's capacity to accept and utilize the data in preparation of the Integrated Report is dependent upon a variety of factors and the use of all data brought to our attention may not be possible. Data must have been collected after January 1, 2013 and must meet the basic acceptability specifications listed above. Data must be provided in an electronic format such as STORET, Excel or Access.

To whom do I send the data?

Submit microbiological data and supporting information listed above by September 15, 2015 to Chris Skalski, chris.skalski@epa.ohio.gov, Ohio EPA/DSW, P.O. Box 1049, Columbus, Ohio 43216-1049.

Submit biological, physical, and chemical water quality data and supporting information listed above by July 15, 2015, to Jeff DeShon, <u>jeffrey.deshon@epa.ohio.gov</u>, Ohio EPA/Groveport Field Office, 4675 Homer-Ohio Lane, Groveport, Ohio 43125.

D6.2 Web Page Announcing 2016 Integrated Report Preparation

As shown below, Ohio EPA announced the preparation and anticipated schedule⁹ of the 2016 Integrated Report on its website (http://www.epa.ohio.gov/dsw/tmdl/OhioIntegratedReport.aspx).

Preparation of 2016 Integrated Report is Underway

Ohio EPA is preparing the 2016 Integrated Report, which fulfills the State's reporting obligations under Section 305(b) (33 U.S.C. 1315) and Section 303(d) (33 U.S.C. 1313) of the Federal Clean Water Act. The report will indicate the general condition of Ohio's waters and list those waters that are currently impaired and may require Total Maximum Daily Load (TMDL) development in order to meet water quality standards.

When will the report be completed?

Major project milestones and expected dates for completion are:

Refine methodologies / compile data	June - October 2015
External Level 3 credible data are due to Ohio EPA	July 15, 2015
Prepare list / internal review	October - December 2015
Public notice draft 303(d) list	December 2015 – January 2016
Respond to comments / prepare final list	February - March 2016
Submit to U.S. EPA Region V for approval	April 1, 2016

Please continue to check this Web site for updates.

⁹ Due to a variety of factors, the 2016 Integrated Report did not follow the originally anticipated schedule.

D6.3 Notice of Availability and Request for Comments CWA Section 303(d) TMDL Priority List for 2016

[TO BE ADDED WHEN AVAILABLE]

Section

Evaluating Beneficial Use: Human Health (Fish Consumption)

E1. Background

The State of Ohio has operated a formal Fish Consumption Advisory (FCA) Program since 1993. Since July 2002, the program's technical and decision-making expertise has been housed at Ohio EPA. The risk assessment protocols used were developed in the early 1990s under the auspices of the Great Lakes Governors Association.

Ohio has adopted human health water quality standards (WQS) criteria to protect the public from adverse impacts, both carcinogenic and non-carcinogenic, due to exposure via drinking water (applicable at public water supply intakes) and to exposure from the contaminated flesh of sport fish (applicable in all surface waters). The latter criterion is called the non-drinking water human health criterion. The purpose of that criterion is to ensure levels of a chemical in water do not bioaccumulate in fish to levels harmful to people who catch and eat the fish. The relationship of the non-drinking water human health criterion to the FCA risk assessment protocols is explained below.

E2. Rationale and Evaluation Method

U.S. EPA's guidance for preparing the 2006 Integrated Report (IR) states:

Although the CWA [Clean Water Act] does not explicitly direct the use of fish and shellfish consumption advisories or NSSP [National Shellfish Sanitation Program] classifications to determine attainment of water quality standards, states are required to consider all existing and readily available data and information to identify impaired segments on their section 303(d) lists. For purposes of determining whether a segment is impaired and should be included on a section 303(d) list, EPA considers a fish or shellfish consumption advisory, a NSSP classification, and the supporting data to be existing and readily available data and information that demonstrates non-attainment of a section 101(a) "fishable" use when:

- the advisory is based on fish and shellfish tissue data,
- a lower than "Approved" NSSP classification is based on water column and shellfish tissue data (and this is not a precautionary "Prohibited" classification or the state water quality standard does not identify lower than "Approved" as attainment of the standard),
- the data are collected from the specific segment in question, and
- the risk assessment parameters (e.g., toxicity, risk level, exposure duration and consumption rate) of the advisory or classification are cumulatively equal to, or less protective than those in the State's WQS" (U.S. EPA, 2005).

Ohio's WQS regulations do not describe human consumption of sport fish as an explicit element of aquatic life protection. However, the WQS regulations do include human health criteria that are applicable to all surface waters of the State. Certain of these criteria are derived using assumptions about the bioaccumulation of chemicals in the food chain and the criteria are intended to protect people from adverse health impacts that could arise from consuming fish caught in Ohio's waters. To determine when and how waters should be listed as impaired because of FCAs, the risk assessment parameters on which the human health WQS criteria are based were compared with those used in the Ohio FCA program. If the State has issued an advisory for a specific water body and that advisory is equal to or less protective than the State's WQS, then one can assume there is an exceedance of the

WQS. On the other hand, if the advisory is more protective than the WQS, one cannot assume that the issuance of the advisory indicates an exceedance of the WQS. Figure E-1 illustrates this point.

Figure E-1. Illustration of the relationship among the WQS values, the values that trigger issuance of FCAs and the resulting decision regarding water body impairment associated with an FCA.

A fish consumption advisory is determined based on the quantity of a chemical in fish, such as micrograms of chemical per kilogram of fish tissue ($\mu g/kg$). WQS, on the other hand, are expressed as the quantity of chemical in water, such as micrograms of chemical per liter of water ($\mu g/L$). The information used to calculate the human health non-drinking WQS criterion can be used to calculate a maximum safe fish concentration. The fish concentration value can then be directly compared to the FCA program values to determine whether the advisory is less or more protective than the WQS criterion. The values in Table E-1 make this comparison for chemicals for which there are both an FCA and an Ohio human health non-drinking water criterion. Because Ohio human health criteria differ between the Lake Erie and Ohio River basins, separate comparisons are presented.

These constituents shown in Table E-1 were chosen based on U.S. EPA's recommendations on page 53 of its 2006 IR Guidance (http://www.epa.gov/sites/production/files/2015-10/documents/2006irg-report.pdf; U.S. EPA, 2006a). Hexachlorobenzene and mirex were added because of historic fish tissue contamination with those contaminants.

The table demonstrates that the levels of fish tissue contaminants that trigger a fish advisory have little obvious relation to the levels of fish tissue contaminants on which the WQS criteria are based. This discrepancy exists because different assumptions about fish consumption rates are made in calculating water quality standards than in issuing fish advisories. For example, the fish consumption rate used to calculate the Ohio River Basin WQS criteria is 17.5 grams per day. The fish consumption rate used to calculate a "one meal per week" advisory recommendation is 32.6 grams per day. These values are not the same because the WQS criteria fish consumption rates are based on nutritional studies that attempt to capture approximately how much sport caught fish people are eating, whereas the fish consumption advisory rates are meant to advise people how much fish they can safely consume.

Table E-1. Comparison between fish concentration values and FCA program values.

Basin / Parameter	Fish concentration on which the WQS is based ¹	Range of fish concentrations triggering an "eat no more than one meal per week" advisory	Range of fish concentrations triggering an "eat no more than one meal per month" advisory
Lake Erie / PCB	23 μg/kg	50 - 220 μg/kg	221 - 1,000 μg/kg
Ohio River / PCB	54 μg/kg	50 - 220 μg/kg	221 - 1,000 μg/kg
Lake Erie / mercury	350 μg/kg	110 - 220 μg/kg	221 - 1,000 μg/kg
Ohio River / mercury	1,000 μg/kg	110 - 220 μg/kg	221 - 1,000 μg/kg
Lake Erie / DDT	140 μg/kg	500 - 2,188 μg/kg	2,189 – 9,459 μg/kg
Ohio River / DDT	320 μg/kg	500 - 2,188 μg/kg	2,189 – 9,459 μg/kg
Lake Erie / Chlordane	130 μg/kg	500 - 2,188 μg/kg	2,189 – 9,459 μg/kg
Ohio River / Chlordane	310 μg/kg	500 - 2,188 μg/kg	2,189 – 9,459 μg/kg
Lake Erie / Hexachlorobenzene	29 μg/kg	800 - 3,499 μg/kg	3,500 - 15,099 μg/kg
Ohio River / hexachlorobenzene	67 μg/kg	800 - 3,499 μg/kg	3,500 - 15,099 μg/kg
Lake Erie/ mirex	88 μg/kg	200 - 874 μg/kg	875 - 3,783 μg/kg
Ohio River/ mirex	200 μg/kg	200 - 874 μg/kg	875 - 3,783 μg/kg

Values	Advisory is less protective than the WQS criterion, WQS exceeded, water body impaired
Values	Advisory is more protective than WQS criterion, WQS not exceeded, no impairment from FCA
Values	Advisory may be more, or less, protective than WQS criterion

U.S. EPA stipulates that the risk assessment parameters used to categorize fish tissue contaminant data must be at least as protective as those used in the WQS-based fish concentrations. Fish advisory contaminant levels are not directly related to the WQS criteria contaminant levels and in some cases are not as protective. Therefore, Ohio EPA has elected to directly compare fish tissue data with the WQS criteria calculations shown in the above table, instead of using advisory-based categorizations.

The following steps were utilized to determine a 303(d) list category for waters based on fish tissue contaminant data:

Step 1: Determine available data

All data in the fish tissue database were evaluated for the 2016 IR. The most recent 10 years of data collections, 2005-2014, were used for making category 1 and category 5 determinations. In cases where multiple years of data were available in that 10-year window, all data were weighted equally. In cases where the only data available were older than 2005, the category determined by those data became historical (i.e., impaired-historical or unimpaired-historical).

¹ See Section E4 for an explanation of how these concentrations were calculated.

Ohio's Credible Data Law states that all data greater than five years in age will be considered historical and that it can be used as long as the director has identified compelling reasons as to why the data are credible. In the case of fish tissue, the use of data older than five but ten or fewer years old is necessary. This is because not enough fish tissue samples are gathered from enough locations each year to conduct a thorough assessment of contaminant levels in fish tissue across the state. Frequently, multiple sampling years are needed to make a determination about issuing or rescinding an advisory. Owing to limited staff time and budget resources, it sometimes takes over five years to revisit a location and collect more fish tissue samples. A more complete picture of contaminants in fish tissue is presented when data are utilized that reach back 10 years.

Step 2: Determine fish tissue contaminant concentrations

For streams in each assessment unit (AU)², a weighted average based on species and trophic level was calculated for each contaminant. One year of data was considered adequate to categorize the fish as impaired or unimpaired. Inland lakes are considered a component of the assessment unit(s) in which they are geographically located, so sample results may affect the assessment status of the AU(s) and the index scores for the AU(s). Inland lakes are also analyzed individually; results are displayed in Table E-12.

Step 3: Determine adequate species data

In order to assess an AU as category 1 or 5, at least four samples from that AU are needed, with at least two samples from each of trophic levels three and four. An exception was made for AUs with 10 or more samples from one trophic level and only one sample from the other trophic level.

A geometric mean was calculated for each species and then a weighted average was calculated for each trophic level. A weighted average for each AU was then calculated using the consumption rates found in the water quality criteria calculations. That weighted average was then compared against the contaminant levels listed in Table E-1 and categorized as category 1 or 5.

In cases where those data requirements were not met, an AU was classified as category 3i. In cases where no data were available, an AU was classified as category 3.

This calculation methodology is derived from the methodology described in Section 4.3.2 of the document <u>Guidance for Implementing the January 2001 Methylmercury Water Quality Criterion</u>, Final, U.S. EPA Office of Science and Technology, EPA-823-R-09-002, January 2009 (http://www.epa.gov/waterscience/criteria/methylmercury/pdf/guidance-final.pdf).

For the Lake Erie Basin:

$$C_{avgLEB} = \frac{3.6 * C_3 + 11.4 * C_4}{15} = 0.27 \ mg/kg$$

² Assessment units include both watershed assessment units (12-digit hydrologic units) and large river assessment units (generally rivers that drain more than 500 square miles).

For the Ohio River Basin:

$$C_{avgORB} = \frac{11.8 * C_3 + 5.7 * C_4}{17.5} = 0.18 \, mg/kg$$

Where:

 C_3 = average concentration for trophic level 3

C₄ = average concentration for trophic level 4

Table E-2. Example data for calculating a weighted average fish tissue value.

Species	Trophic Level	Number of Samples	Geometric mean mercury concentration (mg/kg)
Black crappie (<i>Pomoxis nigromaculatus</i>)	3	1	0.085
Bluegill sunfish (<i>Lepomis macrochirus</i>)	3	2	0.098
Channel catfish (Ictalurus punctatus)	3	2	0.145
Common carp (Cyprinus carpio)	3	3	0.120
Largemouth bass (<i>Micropterus salmoides</i>)	4	3	0.212
Smallmouth bass (<i>Micropterus dolomieu</i>)	4	1	0.421
Spotted bass (<i>Micropterus punctulatus</i>)	4	1	0.347

Step 4: Determine appropriate assessment unit divisions

It should be recognized that in determining impairment status based on AUs instead of individual water bodies, extrapolations to water bodies without data are made. In some cases, water bodies that have no data will be categorized as impaired if they are within an impaired AU.

Inland lakes are treated as individual water bodies for impairment purposes regardless of whether they are entirely contained within an AU or straddle more than one AU and results for individual lakes are shown in Table E-12. In addition, any AU containing all or part of an impaired inland lake was considered to be not supporting the beneficial use (see Step 2 above for further explanation).

Step 5: Categorize water bodies within assessment units

Category 5 – Impaired

Any AU meeting the data requirements in step 3 with a weighted average fish tissue concentration of PCBs, mercury, DDT, chlordane, or hexachlorobenzene above the WQS-based fish tissue concentration is placed into category 5. When the data indicating impairment are older than 10 years, the AU remains impaired but is considered impaired-historical, category 5h³.

³ An "h" subcategory could indicate one of two possibilities. In IRs prior to 2010, when Ohio reported on the larger assessment units, categories were assigned based on data collected anywhere in that unit. For the 2010 analysis, the 2008 category was assigned to each of the new, smaller units. If the original data were collected before 1999,

Category 1 – Not Impaired

To be categorized as category 1, not impaired, an AU must meet the data requirements in step 3 and the weighted average concentration of a contaminant must be below the threshold that would trigger an impairment. AUs that had previously been considered category 1, but with no data since 2005, were reclassified as Category $1h^2$.

Category 3 – Insufficient or No Data

Any AU in which current data are available but those data are insufficient according to step 3 (to categorize the AU as category 1 or 5), the AU was listed as category 3i. If no data were available for an AU, the category was listed as 3. If an AU had previously been classified as category 3 or 3i and there were no data in the AU since 2005, the AU was classified as category 3.

Please see Figure E-2 for a summary of the procedure detailed previously.

Figure E-2. Flow chart for the categorization of fish tissue data for the IR.

_

a re-analysis of the data could not be completed for the 2010 report, so the smaller units retained the category of the larger unit. In some cases, the data were collected within the smaller assessment unit and in other cases they were not. For the older data, a distinction between the two could not be made for this report. In addition, data collected prior to 2005 are considered historical in the 2016 analysis.

E3. Results

Fish tissue data for six contaminants were reviewed to determine an IR attainment status. The methodology for selecting, reviewing and categorizing fish tissue data is given in Section E2. The six contaminants reviewed were mercury, PCBs, chlordane, DDT, mirex and hexachlorobenzene. These contaminants were chosen for review based on current and recent fish consumption advisories in Ohio caused by these contaminants, as well as existing human health WQS criteria for the six contaminants.

There were a total of 152 changes to the human health attainment statuses of assessment units for the 2016 IR which are summarized in Table E-3. The primary reasons for change in status include data having become historical and the collection and analysis of new information.

Table E-3. A summary of changes in attainment status from 2014 to 2016 IR.

Rea	Reason for change	
Dat	a have become historical	29
	Category 1 to 1h	12
	Category 3i to 3	11
	Category 5 to 5h	6
Nev	v data	123
	Became category 1	63
	Became category 3i	31
	Became category 5	29
Tot	al changes	152

Detailed results are presented in Tables E-4 through E-12. Detailed information on specific fish consumption advisories including geographic extent of the advisory, type and size of fish affected and consumption advice can be found at http://www.epa.ohio.gov/dsw/fishadvisory/index.aspx.

Table E-4 lists waters impaired because fish tissue levels of PCBs or mercury exceed the threshold level upon which the WQS criterion is based, while Table E-5 includes those not impaired. Table E-6 lists water bodies identified as impaired for this use on a previous 303(d) list that are no longer considered impaired, either because of new data or the updated methodology described in Section E1. There are three WAUs in Ohio with significant pollution resulting in 303(d) listings from other contaminants that affect fish tissue, as shown in Table E-7. Remediation activities on most of these water bodies are underway. In Tables E-8 and E-9, the data for all these locations have become historical and new data would need to be collected before a current impairment status can be determined. Since age of data alone is not a reason for delisting, the water bodies in Table E-9 remain on the 303(d) list. Table E-10 lists waters with current fish tissue data where inadequate samples exist to determine level of impairment. Sites in Table E-10 have never had sufficient data for assessment, now or in the past. Table E-11 lists large rivers and their impairment status. Table E-12 lists inland lake impairment status.

Table E-4. Waters not supporting the human health use because levels of PCBs or mercury in fish tissue exceed the threshold level upon which the WQS criterion is based. These waters are category 5.

Water Body (Category 5: Impaired)	Assessment Unit	Pollutant

E4. Supplemental Information

E4.1 Calculation of Fish Concentrations from Water Quality Standards Inputs

For carcinogens:

$$Fish\ Concentration(mg/kg) = \frac{\left\lfloor \frac{Cancer\ Risk\ Level}{q1*\left(\left(mg/kg/d\right)^{-1}\right)}\right\rfloor \times Body\ Weight\ (kg)}{Fish\ Consumption\ (kg/d)}$$

For noncarcinogens:

Fish Concentration(mg/kg) =
$$\frac{RfD(mg/kg/d) \times Body \ Weight(kg) \times RSC}{Fish \ Consumption(kg/d)}$$

For wildlife:

Fish Concentration(mg/kg)= Wildlife WQC(mg/L)× BAF
$$TL_n(L/kg)$$

Lake Erie Drainage Basin

	Mercury	Chlordane	DDT	PCBs	Hexachloro- benzene	Mirex
HHWQC	3.1 ng/L	2.4 μg/L	0.15 ng/L	0.026 ng/L	0.45 ng/L	0.074 ng/L

Derivation of Concentrations

Lake Erie Drainage Basin Mercury Human Health Fish Concentration

$$\frac{1E - 04(mg/kg/d) \times 65(kg) \times 0.8}{0.015(kg/d)} = 0.35(mg/kg) = 350(\mu g/kg)$$

Lake Erie Drainage Basin Mercury Wildlife Fish Concentration

Trophic Level 3:

$$1.3E - 06(mg/L) \times 27,900(L/kg) = 0.036(mg/kg) = 36(\mu g/kg)$$

Trophic Level 4:

$$1.3E - 06(mg/L) \times 140,000(L/kg) = 0.18(mg/kg) = 180(\mu g/kg)$$

Lake Erie Drainage Basin Chlordane Human Health Fish Concentration

$$\frac{\left[\frac{1E - 05}{0.35(mg/kg/d)^{-1}}\right] \times 70(kg)}{0.015(kg/d)} = 0.13(mg/kg) = 130(\mu g/kg)$$

Lake Erie Drainage Basin DDT Human Health Fish Concentration

$$\frac{\left[\frac{1E - 05}{0.34(\text{mg/kg/d})^{-1}}\right] \times 70(\text{kg})}{0.015(\text{kg/d})} = 0.14(\text{mg/kg}) = 140(\mu\text{g/kg})$$

Lake Erie Drainage Basin DDT Wildlife Fish Concentration

Trophic Level 3:

$$1.1E - 08(mg/L) \times 376,400(L/kg) = 0.0041(mg/kg) = 4.1(\mu g/kg)$$

Trophic Level 4:

$$1.1E - 08(mg/L) \times 1,140,000(L/kg) = 0.012(mg/kg) = 12(\mu g/kg)$$

Lake Erie Drainage Basin PCB Human Health Fish Concentration

$$\frac{\left[\frac{1E - 05}{2.0(\text{mg/kg/d})^{-1}}\right] \times 70(\text{kg})}{0.015(\text{kg/d})} = 0.023(\text{mg/kg}) = 23(\mu\text{g/kg})$$

Lake Erie Drainage Basin PCB Wildlife Fish Concentration

Trophic Level 3:

$$1.2E - 07(mg/L) \times 520,900(L/kg) = 0.062(mg/kg) = 62(\mu g/kg)$$

Trophic Level 4:

$$1.2E - 07(mg/L) \times 1,871,000(L/kg) = 0.22(mg/kg) = 220(\mu g/kg)$$

Lake Erie Drainage Basin Hexachlorobenzene Human Health Fish Concentration

$$\frac{\left[\frac{1E - 05}{1.6(mg/kg/d)^{-1}}\right] \times 70(kg)}{0.015(kg/d)} = 0.029(mg/kg) = 29(\mu g/kg)$$

Lake Erie Drainage Basin Mirex Human Health Fish Concentration

$$\frac{\left[\frac{1E - 05}{0.53(mg/kg/d)^{-1}}\right] \times 70(kg)}{0.015(kg/d)} = 0.088(mg/kg) = 88(\mu g/kg)$$

Ohio River Drainage Basin

	Mercury	Chlordane	DDT	PCBs	Hexachloro- benzene	Mirex
HHWQC	12 ng/L*	21 ng/L	5.9 ng/L	1.7 ng/L	7.5 ng/L	0.11 ng/L

Relative Source Contribution Factor (RSC)	N/A	N/A	N/A	N/A	N/A	N/A

^{*} Based on the FDA action level of 1 mg/kg divided by the BCF of 83,333 L/kg.

Ohio River Drainage Basin Mercury Fish Concentration

1 mg/kg based on FDA action level

Ohio River Drainage Basin Chlordane Fish Concentration

$$\frac{\left[\frac{1E - 05}{0.35(mg/kg/d)^{-1}}\right] \times 70(kg)}{0.0065(kg/d)} = 0.31(mg/kg) = 310(\mu g/kg)$$

Ohio River Drainage Basin DDT Fish Concentration

$$\frac{\left\lfloor \frac{1E - 05}{0.34(mg/kg/d)^{-1}} \right\rfloor \times 70(kg)}{0.0065(kg/d)} = 0.32(mg/kg) = 320(\mu g/kg)$$

Ohio River Drainage Basin PCB Fish Concentration

$$\frac{\left\lfloor \frac{1E - 05}{2.0 (mg/kg/d)^{-1}} \right\rfloor \times 70 (kg)}{0.0065 (kg/d)} = 0.054 (mg/kg) = 54 (\mu g/kg)$$

Ohio River Drainage Basin Hexachlorobenzene Fish Concentration

$$\frac{\left[\frac{1E - 05}{1.6(mg/kg/d)^{-1}}\right] \times 70(kg)}{0.0065(kg/d)} = 0.067(mg/kg) = 67(\mu g/kg)$$

Ohio River Drainage Basin Mirex Fish Concentration

$$\frac{\left\lfloor \frac{1E - 0.5}{0.53 (mg/kg/d)^{-1}} \right\rfloor \times 70 (kg)}{0.0065 (kg/d)} = 0.20 (mg/kg) = 200 (\mu g/kg)$$

Fish Tissue Concentrations for Determining Impairment for the 2016 IR (μg/kg)

	Lake Erie HH	Lake Erie – wildlife TL3	Lake Erie – wildlife TL4	Ohio River
Mercury	350	36	180	1000
Chlordane	130	N/A	N/A	310
DDT	140	4.1	12	320
PCBs	23	62	220	54
Hexachlorobenzene	29	N/A	N/A	67
Mirex	88	N/A	N/A	200

E4.2 What's the Difference between the Fish Consumption Advisory Decision and the Impairment Decision?

Some question may arise as to how the methodology for determining impairment status for the 2016 IR for fish tissue relates to the fish advisories issued by the State of Ohio. Rather than building on fish consumption advisory decisions, the revised methodology draws directly from the fish tissue contaminant database. This change was possible because of better accessibility to the raw data.

In short, the basis for determining impairment for the IR for fish tissue is similar but unrelated to the basis for determining advisories. The WQS calculations assume a certain amount of fish consumption and ensure that level of consumption is safe. The advisory calculations determine what level of fish consumption is safe. Therefore, both are protective of human health. However, advisories and IR impairment status are not directly related.

Advisory thresholds are given as one meal per week, one meal per month, one meal every other month and do not eat. Each threshold is associated with a particular contaminant concentration that is based on consuming an eight-ounce meal. For both PCBs and mercury, those thresholds are 50 parts per billion (ppb) for one meal per week, 220 ppb for one meal per month, 1,000 ppb for one meal every other month and 2,000 ppb for do not eat.

The thresholds used for determining IR categories are based on water quality standards for human health. The water quality standards assume that people are eating a certain quantity of different types of fish over time. The Lake Erie basin WQS calculations for mercury and PCBs assume that people are eating 15 grams of fish per day. The Ohio River basin calculations for PCBs and mercury assume that people are eating 6.5 grams of fish per day.

Advisory thresholds are prescriptive, indicating to people how much fish is safe to eat given a certain level of fish contamination. Water quality standard-based thresholds are descriptive, indicating how much contamination is acceptable in fish given that people are eating a certain amount of certain types of fish. In other words, the advisories tell people how much fish they can safely eat and the water quality standards assume how much fish people are eating and use that information to calculate a "safe" level of contamination in fish.

U.S. EPA, in its guidance on developing the IR, indicates that water quality standards are to be used as the basis for determining impairment categories for fish tissue. Because the assumptions used to calculate the advisories are different than the assumptions used to calculate the WQS, this results in cases where some water bodies have advisories against fish consumption but are not listed as impaired and some water bodies are listed as impaired but no fish advisory is in place. This situation is demonstrated in the following table:

Parameter	Lake Erie Basin	Ohio River Basin	1 meal per week advisory	1 meal per month advisory		
Fish Consumed	15 grams/day	6.5* grams/day	32.6 grams/day	7.6 grams/day		
Maximum Allowable Fish Concentration						
PCB Threshold	23 ppb	54 ppb	50 ppb	220 ppb		
Mercury Threshold	350 ppb	1000 ppb	50 ppb	220 ppb		

* This value is under review in the current proposed WQS rule update for 3745-1. The proposed value of 17.5 g/day was used in calculating the proportion of trophic level 3 and 4 fish consumed in the Ohio River basin, but was not used in developing the thresholds for determining impairment status.

The reason the thresholds are different between the two basins is that the assumed fish consumption levels are different. The reason the water quality standard thresholds are different from the advisory thresholds is both because the fish consumption levels are different and because for PCBs, a cancer slope factor is used to calculate the water quality standard criteria, which is stricter than the health protection value used to calculate the advisory threshold.

Data for smallmouth bass in Conneaut Creek provide an example where there is an advisory but the water body is not impaired.

Channel catfish in Pymatuning Reservoir show a case where there is no advisory but the water is listed as impaired.

F1. Background

Prior to the 2002 Integrated Report (IR), the reporting of recreation use (RU) impairment in Ohio was sporadic. Clean Water Act (CWA) Section 305(b) reports (1998 and earlier) may have included an indication of the potential for RU impairment in various streams, but a comprehensive listing of recreational use impairment was not included. The 2002 IR employed a uniform methodology to examine readily available data on fecal coliform counts. This approach was based on counting the number of exceedances of the secondary contact RU maximum criterion [5,000 colony forming units (cfu)/100 mL fecal coliform or 576 cfu/100 mL *Escherichia coli* (*E. coli*)]. Any assessment unit with five or more samples over the last five years above these values was listed as having an impaired RU.

The 2004 IR adopted a more statistically robust methodology for assessing the RU attainment of the state's surface waters linked more directly to the applicable water quality standards. The methodology adopted in 2004 continued to be used through the 2008 IR. The 2008 IR also included a preview of changes anticipated at the time for the 2010 report based on the expectation that the watershed assessment unit (WAU) would change from a larger watershed size (11-digit HUC) to a smaller watershed size (12-digit HUC) and on four anticipated revisions to the water quality standards: 1) dropping the fecal coliform criteria; 2) creation of a tiered set of classes of primary contact recreation waters based on RU intensity; 3) revision of the geometric mean averaging period; and 4) extension of the recreation season. Revisions to the water quality standards pertaining to the RU were adopted on December 15, 2009. The linkage of the methodology to the Ohio water quality standards (WQS) is summarized in Table F-1 and subsequent text. The RU assessment method employed in this report is essentially the same as used in the 2010, 2012 and 2014 reports.

Table F-1. Summary of the RU assessment methods.

	illiary of the RO assessment methods.	
Bathing Wate	ers	
Indicator	Criterion (Table 7-13, OAC 3745-1-07)	Assessment Method Summary
E. coli	Seasonal geometric mean <i>E. coli</i> content* based on samples from the recreation season within a calendar year is 126 cfu/100 mL; single sample maximum is 235 cfu/100 mL.	Applied to the three Lake Erie assessment units, exceedance of the geometric mean bathing water criterion or an exceedance of the single sample maximum for more than 10 percent of the recreation season is considered an impairment of the bathing water use.
Primary Cont	act and Secondary Contact	
Indicator	Criterion (Table 7-13, OAC 3745-1-07)	Assessment Method Summary
E. coli	Seasonal geometric mean <i>E. coli</i> content* based on samples from the recreation season within a calendar year is as follows: Primary Contact Waters Class A: 126 cfu/100 mL Class B: 161 cfu/100 mL Class C: 206 cfu/100 mL Secondary Contact Waters All:1030 cfu/100 mL	Applied to streams and inland lakes. Data from a recreation season are assessed on a site-by-site basis and compared to the applicable geometric mean <i>E. coli</i> criterion whenever more than one sample result is available for a WAU. Assessment units (AUs) are considered to be in full attainment if all sites assessed within the AU meet the applicable geometric mean criterion and in non-attainment if one or more sites assessed within the AU exceed the applicable geometric mean criterion.

^{*}E. coli concentrations are expressed in colony forming units (cfu) per 100 milliliters (mL)

F2. Evaluation Method

Lake Erie (Shoreline)

Attainment of the RU designation for the three Lake Erie assessment units (LEAUs) was based upon examination of *E. coli* data from public bathing beaches provided by the Ohio Department of Health (ODH). Routine bacteria monitoring is performed by local health districts, ODH and the Northeast Ohio Regional Sewer District (NEORSD) in order to monitor bacteria levels at public bathing beaches and advise the public when elevated bacteria are present that represent an increased risk of contracting waterborne illness as a result of exposure to pathogens while recreating in the water. This monitoring takes place at 65 public beaches in eight coastal counties. The public can access the ODH Beachguard website to view beach advisory postings and bacteria monitoring data from monitored beaches at http://publicapps.odh.ohio.gov/BeachGuardPublic/Default.aspx. The website is updated daily during the summer recreation season.

Since 2006, beach advisory recommendations have been based upon exceedance of the single sample maximum *E. coli* criterion of 235 cfu/100 mL, consistent with provisions of the 2004 federal Beaches Environmental Assessment and Coastal Health (BEACH) Act rule as well as the *E. coli* criterion applicable for bathing waters in Ohio's water quality standards. Bacteria data collected by local or state health agencies at public beaches during the recreation season from 2011 through 2015 were included in the analysis. Ohio's water quality standards define the recreation season as May 1 through October 31, though Lake Erie beach monitoring typically is focused between the Memorial Day and Labor Day weekends.

Each of the 22 public beaches that have traditionally been sampled as part of the Lake Erie bathing beach monitoring program (Figure F-1) was individually analyzed to evaluate the percentage of recreation days during which the bathing water single sample maximum criterion of 235 cfu/100 mL was exceeded, since this is the criterion used by health departments to post a health advisory at a given beach. The frequency of beach advisory postings is a direct measure of RU impairment, since potential users may often be discouraged from utilizing a beach on days when a health advisory is posted or to avoid certain beaches altogether that are prone to frequent advisories. The locations of beaches in Erie and Sandusky Counties are depicted in Figure F-2, while those beaches located in Cuyahoga and Lorain Counties are depicted in Figure F-3.

As of October 1, 2013, there were 169 public access locations in the eight coastal counties along Ohio's Lake Erie coastline. These public access points do not all include a swimming beach, as some are for boat access, fishing access, parks, wildlife viewing areas, etc. The Ohio Department of Natural Resources (ODNR) publishes a Lake Erie Public Access Guide that can be accessed from this web address: http://coastal.ohiodnr.gov/gocoast. This report used data collected from 65 different beaches along the coast as depicted in Figures F-1 through F-3.

The total number of recreation days in a recreation season for any particular beach was determined by adding the number of days beginning with the first day of sampling and ending with Labor Day, or the date the final sample was collected (whichever was later). The total number of days that a beach exceeded the single sample maximum *E. coli* criterion of 235 cfu/100 mL during the recreation season (as defined above) was tallied. A measured exceedance was assumed to continue until a subsequent sample documented that the criterion was not exceeded. Similarly, a beach was presumed to meet the criterion following a measurement that met the criterion until a subsequent sample was found to

exceed the criterion. Sampling frequency varied from year-to-year and from beach-to-beach. A sampling frequency of four times per week was typical, though some beaches were sampled daily while the two beaches in the Lake Erie Islands AU were sampled only once per week.

Figure F-1. Lake Erie public beaches sampled under Ohio's bathing beach monitoring program.

Figure F-2. Erie and Sandusky County public beaches sampled under Ohio's bathing beach monitoring program.

Figure F-3. Cuyahoga and Lorain County public beaches sampled under Ohio's bathing beach monitoring program.

The exceedance frequency of the bathing water criterion was determined for each beach over a five-year period (2011-2015) on an annual basis. Results for each individual beach were sorted into the corresponding LEAU for the purpose of determining the attainment status of each of the three LEAUs. The assessment status for each LEAU was based upon whether the frequency of exceedance of the single sample maximum *E. coli* criterion was greater than 10 percent of the recreation season, as described in the Table F-2 below.

Table F-2. Determining assessment status of Lake Erie shoreline AUs.

LEAU Status	Attainment Status of Individual Beaches
Full	Frequency of advisory postings less than 10 percent of recreation season for all of the beaches in the AU for all years assessed
Non	Frequency of advisory postings more than 10 percent of recreation season for one or more of the beaches in the AU for one or more of the years assessed

A 10 percent exceedance frequency was used as the threshold for attainment determination in the last five assessment cycles and has its origins in the water quality standards as well as Ohio's 1998 State of the Lake Report prepared by the Ohio Lake Erie Commission (Ohio LEC 1998). While the stated goal in the State of the Lake report for beaches is to have clean beaches all of the time (no days under advisement), the report considered having ten or fewer days under advisement to be "excellent" (note that ten days translates to 10 percent of the season based on a 100-day season). The Ohio Lake Erie Commission's latest edition of the State of the Lake Report (Ohio LEC 2004) continues to use these benchmarks in rating the swimmability of Lake Erie beaches along Ohio's 312-mile shoreline. The 2016 IR also continues to use these criteria in determination of impairment at the assessment unit level. In addition, statistical summaries are included in Tables F-5 and F-6 for individual beaches to provide more detail and allow performance comparisons among individual beaches.

Rivers and Streams

The 2016 RU impairment list was developed using ambient *E. coli* survey data collected from May 2011 through October 2015 by Ohio EPA as well as from ambient stream data provided by municipal dischargers that were collected at upstream and downstream monitoring stations relative to their primary discharge location as required by their National Pollutant Discharge Elimination System (NPDES) permit and reported in the Surface Water Information Management System (SWIMS) database. *E. coli* data from dischargers, while previously limited in quantity since permits had historically been based on monitoring for fecal coliform, has become more numerous as *E. coli* monitoring has replaced fecal coliform monitoring in most NPDES permits.

Approximately 18,400 *E. coli* bacteria records were evaluated in this analysis. Data were sorted into their respective 12-digit WAUs and large river assessment units (LRAUs) using a geo-spatial analysis of the latitude/longitude data (and other geographical data if needed) associated with each *E. coli* value. Data within a WAU were further sorted by sampling location and date (calendar year) on which they were collected. Figure F-4 demonstrates the sampling coverage that would be typical for part of a study area. In this case, there are five 12-digit WAUs depicted that drain to one LRAU, the Walhonding River. Each of the five WAUs was sampled in 2010 at one location (depicted by yellow dots) toward the downstream end of the primary tributary in the WAU. Four sampling locations (green dots) are dispersed along the 16-mile stretch of the Walhonding River depicted for an average sampling density of one site per four miles of river length for the Class A primary contact recreation water. Sites were generally sampled at least on five different occasions over the course the 2010 recreation season, though some sites were sampled more frequently.

Figure F-4. Example of bacteria sampling locations, upper Walhonding River study area (2010).

RU assessment determinations for rivers and streams are based on the following two-step process: site-by-site analysis and assessment unit analysis.

Site-by-Site Analysis

E. coli data from each site were compared to the geometric mean *E. coli* criterion applicable to the particular site, considering the RU and class (for primary contact recreation or PCR). The geometric mean was calculated using the "geomean" function in Microsoft Excel 2010® on a site-by-site basis using the pooled dataset of all *E. coli* data (minimum of two data points required but typically composed of five samples) from the site during a single recreation season. When data were available for multiple recreation seasons, the data from each season were independently analyzed for each recreation season to determine the geometric mean for each season. Further details are listed as follows:

- Data collected outside of the recreation season as defined in Ohio's WQS (May 1st through October 31st) were excluded from the analysis.
- Certain qualified values, such as sample results that exceeded proper holding time or those that have otherwise been indicated to have significant quality assurance deficiencies, were also excluded from the analysis.
- Values reported as "too numerous to count" ("TNTC") were used in the analysis when it was possible to estimate a value based on the dilutions used and/or the maximum reporting limits.
- Values reported as "greater than" were also used in the analysis. A geometric mean calculated using one or more "greater than" or "TNTC" values in the data set was reported as a "greater than" geometric mean.
- Values reported as "less than" values of greater than 50 were excluded since acceptable test methods can detect much lower concentrations when appropriate dilutions are used in the analysis. Values reported as 50 or less were used in the analysis. The value used in statistical analysis was one-half the reported "less than" value. A value of one was substituted for the purpose of computing the geometric mean in any case where a value of less than one was reported. Geometric means cannot be calculated using data sets that contain a value of zero.
- Results from duplicate B were used for calculation of the geometric mean in cases where duplicate sample results were reported, except if the *E. coli* densities of the duplicate samples were more than five times apart from one another, in which case both values were rejected.

Assessment Unit Analysis

In the second step of the analysis, the assessment status of the WAU or LRAU was determined based on the attainment status of all the individual sites within the assessment unit and within the assessment period (2011-2015) as described in Table F-3 below.

Table F-3. Determining assessment status of WAUs and LRAUs.

AU Assessment Status	Attainment Status of Individual Locations
Full (Category 1)	Sufficient data exist to calculate a geometric mean for at least one location within the WAU (or a minimum of one site for every ~5-7 river miles of a LRAU); applicable geometric mean(s) attain applicable geometric mean criterion at all assessed sites within the AU
Non (Category 5)	Sufficient data exist to calculate a geometric mean for at least one location within the WAU (or a minimum of one site for every ~5-7 river miles of a LRAU); geometric mean(s) exceed applicable geometric mean criterion at one or more assessed sites within the AU
Insufficient Data (Category 3)	No data (category 3) or insufficient data (category 3i) to calculate a geometric mean for any site within the WAU (or for a minimum of one site for every ~5-7 river miles of a LRAU)

Inland Lakes

Inland lakes were assessed in a manner similar to that described above for the rivers and streams. Inland lake data were analyzed on a site-by-site basis, with each resulting geometric mean value compared to the geometric mean criterion applicable to each site. Lake sampling locations generally included a beach and/or open water location, with five to ten samples per location. Inland lakes are considered a component of the assessment unit(s) in which they are geographically located, so sample results from lakes may affect the assessment status of the AU(s) and the index scores for the AU(s).

ODNR, as part of Ohio's Bathing Beach Monitoring Program, monitors *E. coli* levels during the summer at public beaches of lakes located in state parks. While Ohio EPA was unable to establish the level of credibility of these data for use in official listing determinations for this report, a summary of the advisory postings for the 68 beaches monitored in the program is included in Table F-17. Though similar to the beach monitoring program along Lake Erie, there are several differences. Notably, the sampling frequency is much lower at the inland lake beaches compared to the Lake Erie beaches as a result of funding disparity. Secondly, because of the large geographic area, beach samples from inland lakes are analyzed by a multitude of consulting laboratories across the state.

RU Attainment Index Score

The RU attainment index score provides a way to compare the relative difference between the *E. coli* concentrations at sites sampled within an assessment unit and the RU geometric mean criterion that applies to each of the sampled sites. Those assessment units having *E. coli* concentrations that tended to be much greater than the applicable criteria had the lowest scores, while those assessment units having *E. coli* concentrations that attained the applicable criteria, or tended to only slightly exceed the applicable criteria, had the highest scores. An index score was assigned for each site having sufficient data to calculate a geometric mean (i.e., two or more samples) by comparing the geometric mean *E. coli* concentration at the site to the applicable geometric mean criterion based on the scale depicted in Table F-4.

Table F-4. Recreation index score matrix.

Site Geometric Mean	Index Score
Meets criterion	100
Exceeds up to 2x criterion	75
Exceeds more than 2x up to 5x criterion	50
Exceeds more than 5x up to 10x criterion	25
Exceeds more than 10x criterion	0

An average index score was computed for assessment units with multiple site index scores based on data from multiple sites and/or recreation seasons. Index scores are reported in Table F-11 for the LRAUs. When only one site index score was available for an AU, that index score was used to represent the assessment unit. The index score for the AU is based upon the same scale as described above for the index score for a particular site.

F3. Results

Using the methodology outlined in the previous section and available *E. coli* data collected from 65 public beaches along Ohio's Lake Erie 312-mile shoreline (14,294 samples); at hundreds of locations from Ohio's rivers and streams (11,450 samples) including nine of Ohio's largest rivers; and for 21 of Ohio's inland lakes (240 samples) results for the RU attainment analysis are presented in this section.

Samples used in this analysis were collected from 2011 through 2015 during the recreation season of May 1 through October 31.

F3.1 Lake Erie Public Beaches

Information about water quality conditions at Lake Erie public bathing beaches is summarized in Tables F-5 through F-8 and Figure F-5. The location of these beaches is shown in Figures F-1 through F-3. The methodology used for assessing the beaches along Ohio's Lake Erie shoreline is unchanged from the 2010, 2012 and 2014 reports.

Table F-5 contains the seasonal geometric mean *E. coli* levels for 17 public beaches along the coast of Lake Erie's western basin for the past five recreational seasons (2011-2015) while Table F-6 contains the seasonal geometric mean *E. coli* levels for 48 public beaches along the coast of Lake Erie's central basin for the past five recreational seasons (2011-2015).

The seasonal geometric mean *E. coli* criterion for bathing waters was exceeded at fourteen beaches in 2011, thirteen beaches in 2012, twenty-two beaches in 2013, eighteen beaches in 2014 and fifteen beaches in 2015. Six beaches exceeded the seasonal geometric mean bathing water criterion for the entire five year reporting period – Arcadia, Bay View West, Euclid State Park, Lakeshore Park, Lakeview and Villa Angela. Not surprisingly, these beaches had among the most days under a swimming advisory during the 2011-2015 reporting period. Highlighted cells in Table F-5 indicate impairment of the RU at a given beach in a given year. The table also indicates the number of beach advisories for each beach based upon exceedance of the single sample maximum *E. coli* criterion for beaches of 235 cfu/100 mL. This is the threshold that triggers the issuance of beach advisories and has been used since 2006. Use of the single sample maximum *E. coli* criterion for the purpose of issuing beach advisories complies with the federal Beaches Environmental Assessment and Coastal Health (BEACH) Act rule (*Water Quality Standards for Coastal and Great Lakes Recreation Waters*, 69 FR 67217, November 16, 2004), which became effective on December 16, 2004.

In Tables F-7 through F-9, the beaches are arranged alphabetically according to the LEAU in which they are geographically located. The table indicates the number of days (and the percentage for all years) when Ohio's Lake Erie public beaches exceeded Ohio's bathing water single sample maximum criterion compared to the total number of days in the recreation season sampling period.

As depicted in Figure F-5, the frequency with which individual beaches were recommended for a swimming advisory based on elevated bacteria levels above the state water quality standards for the entire five year reporting period (2011-2015) ranged from near zero at South Bass Island State Park and Battery Park beach to nearly 40 percent or more at Arcadia, Bay View West, Edson Creek, Euclid State Park, Lakeshore Park, Lakeview, Sherod and Villa Angela State Park beaches. Considerable variation in the frequency of advisories was observed between beaches and from season-to-season at many beaches. However, several beaches stand out as consistently good performers over the past several recreation seasons, including Battery Park, Bay Park, Catawba Island, Conneaut, East Harbor State Park, Kelleys Island, Lakeside and South Bass Island State Park, which all had a cumulative exceedance frequency under 10 percent. These beaches infrequently exceeded the goal of fewer than 10 days per season under advisement. There were also several beaches that performed consistently poor with four beaches including Bay view East, Edson Creek, Lakeview and Villa Angela beach under advisement approaching or over 50 percent of the time during the past five recreation seasons on a cumulative basis. High variation in bacteria levels was also seen between seasons for some beaches. For example,

Cranberry beach was under advisement for just six days in 2012, but under advisement for 34 days in 2013. Fichtel beach was under advisory eight days in 2012, but was under advisory for 32 days in 2013. The annual median number of days under advisement for all beaches by calendar year was highest in 2013 at 28 days compared to the rest of the reporting years, which had a median number of days under advisory ranging from 17-22 on an annual basis. The annual average geometric mean *E. coli* level for all beaches by year within this reporting cycle ranged from a low of 80.7 in 2011 to a high of 112.0 in 2014.

Impairment of the bathing water RU was determined by pooling data from beaches in each of the three LEAUs and calculating the percentage of days in the recreational season when the *E. coli* criterion was exceeded. A threshold of impairment was set at 10 days per season based upon the Ohio Lake Erie Commission's evaluation system (Ohio LEC 1998). This translates to a seasonal exceedance frequency of 10 percent, as the recreation season at Lake Erie's beaches in Ohio typically runs from Memorial Day weekend through Labor Day weekend. Results are shown in Table F-10. As in previous assessment cycles, the 2016 assessment results indicate that the Lake Erie Islands assessment unit fully supports the RU while the western basin and central basin assessment units do not support the RU. The overall total recreation days in exceedance of the bathing waters criterion on a percentage basis was 15.9 percent in the western basin (15 beaches) and 25.8 percent (48 beaches) in the central basin compared to just 3.1 percent for the Lake Erie Islands (two beaches).

Final draft

Table F-5. Seasonal geometric mean E. coli levels and advisory postings at public Lake Erie shoreline beaches in the western basin.

		2011	20	2012	20	2013	20	2014	20	2015

South Bass Island	5	0	7	0	10	4	9	0	7	2
Whites Landing	16	21	188	33	362	57	158	36	158	45

Days for which no monitoring data were collected are presumed to be in exceedance if the preceding day's bacteria level exceeded the criteria. Unmonitored days are presumed commences, typically in late May though the end of the Labor Day weekend. The number of days posted is determined by counting the number of days a criterion is exceeded. Shaded cells indicate impairment of the RU. Impairment is triggered by an exceedance of the geometric mean criterion on a seasonal basis (seasonal geomean) or if the singlesample maximum criteria (SSM) are exceeded more than 10 percent of the time during a season. The beach season is defined for this analysis as the time E. coli monitoring to meet the criteria when preceded by a monitored day that was below the criterion.

season. The beach season is defined for this analysis as the time E. coli monitoring commences, typically in late May, though the end of the Labor Day weekend. The number of preceding day's bacteria level exceeded the criteria. Unmonitored days are presumed to be below the criteria when preceded by a monitored day that was below the criterion. Empty cells indicate no data were available for the beach during that year. Highlighted cells indicate impairment of the RU. Impairment is triggered by an exceedance of the days posted is determined by counting the number of days a criteria is exceeded. Days for which no monitoring data were collected are presumed to be in exceedance if the geometric mean criterion on a seasonal basis (seasonal geomean) or if the single-sample maximum criteria (SSM) are exceeded more than 10 percent of the time during a

Table F-7. The number of days per season (and the percentage for all years) when Ohio Lake Erie public beaches exceeded Ohio's single sample maximum *E. coli* criterion compared to the total number of days in the sampling period, 2011 – 2015, for the Central Basin AU.

Figure F-5. Frequency of advisory postings at Ohio's Lake Erie public beaches.

Table F-10. Bathing water geometric mean *E. coli* exceedance frequency at 65 Lake Erie public beaches from 2011-2015 (pooled by LEAU to report use support).

	Western Basin	Central Basin	Lake Erie Islands
Number of beaches	15	48	2
Total recreation days	7,400	22,962	930
Total days in exceedance	1,549	5,926	29
Percentage of days in exceedance	15.9%	25.8%	3.1%
Average # of days <i>E. coli</i> criteria exceeded per beach per season ¹	20.9	26.2	1.0
Attainment status	Does not support	Does not support	Full support

¹Calculated by dividing the total days in exceedance in the basin by the total number of beach seasons in the basin. The total number of beach seasons in a basin is equal to aggregated sum of the total number of beaches for which monitoring was conducted during each season for the 2011-2015 reporting period.

F3.2 Rivers and Streams

Approximately 18,400 bacteria measurements were evaluated for the 2016 RU support analysis of streams, rivers and inland lakes in Ohio. Ohio's RU support analysis is based on an examination of *E. coli* data collected in Ohio's rivers, streams and inland lakes during the recreation season.

While the majority of the *E. coli* data used in previous assessment reports were collected by Ohio EPA, this is the first report in which the majority of the data used in the analysis has come from discharger generated data. This is a result of the transition from fecal coliform monitoring requirements to *E. coli* monitoring requirements in NPDES permits following the adoption of *E.coli* criteria in place of fecal coliform criteria in Ohio's water quality standards in 2009. While few facilities were monitoring for *E. coli* shortly following the revised criteria, most facilities are now measuring and reporting *E. coli* values following the expiration of permit compliance schedules. As expected, the amount of data from NPDES sources has grown substantially. In this report, approximately 60 percent of the data are from NPDES dischargers while the remaining 40 percent was generated by Ohio EPA.

Table F-11 provides a summary of Ohio EPA's RU monitoring effort and its translation to use assessment annually for the past five recreation seasons.

Table F-11. Annual Ohio EPA *E. coli* sampling effort and RU assessment (using Ohio EPA data) in Ohio streams, rivers and inland lakes, 2011-2015 recreation seasons.

	2011	2012	2013	2014	2015
number of samples collected by Ohio EPA	1,674	1,173	1,635	1,423	1,231
number of site geometric means computed	276	219	269	222	219
number of unique WAUs assessed	130	92	131	121	115
number of unique LRAUs assessed	3	5	2	1	0

The *E. coli* data used in this report from Ohio EPA was typically collected as part of routine ambient monitoring associated with annual drainage basin surveys conducted around the state. Using the methodology described in Section F2, it was possible to determine the RU attainment status of 697 of the 1,538 (45 percent) WAUs in Ohio based on current data (2011-2015). This figure includes those WAUs in which data were collected between 2011 and 2015, regardless of the category of the AU. Ohio has completed total maximum daily loads (TMDLs) for bacteria in 448 of the 1,538 WAUs in Ohio (29 percent).

On an annual basis, Ohio's current effort typically allows the state to assess the RU of less than 10 percent of the WAUs in the state using data collected by Ohio EPA. At this rate, the maximum current assessment information that will be possible at any given time using Ohio EPA-generated data will be for about half of the state's WAUs, assuming that there is no assessment duplication within any given WAU during any five-year data period and the sampling effort is limited to the minimal amount needed per WAU to make an assessment determination as described in Section F2.

Table E 12	Overall difference	c in the accord	ent of RU attainment	2010 2014
Table F-12.	Overall differences	s in the assessme	ent of RU attainment	. 2010-2010.

	2010 Report		2012 Report		2014 Report		2016 Report	
	Number	Percent	Number	Number	Number	Percent	Number	Percent
total AUs	1,576	100	1,576	100	1,576	100	1,576	100
assessed	487	31	588	37	680	43	713	45
not assessed	1,089	69	988	63	896	57	863	55
supporting use ^a	65	13	88	15	130	19	73	10
not supporting use ^a	422	87	500	85	550	81	640	90

^a Note: The percentage of AUs reported as supporting the RU and not supporting the RU are based on the total AUs that were assessed (e.g., 487 in the 2010 analysis).

The overall attainment and impairment rates and the changes between reporting years are summarized in Table F-12. Attainment and impairment rates in Table F-12 are based on the total number of watersheds for which sufficient data were available in the respective reporting cycle and not on the total number of assessment units in the state. For the 713 assessment units having sufficient data available to determine the RU assessment status in 2016, 10 percent fully supported the use while 90 percent did not support the use. These results are lower, almost half of the total supporting the recreational use in the 2014 cycle, but comparable to the results from previous cycles that consistently show that only a relatively small proportion of the state's watersheds demonstrate full support of the RU.

Table F-13 contains *E. coli* RU geometric mean criteria attainment rates on an individual site basis for primary contact use Class A and Class B sites by year. While there does not appear to be any discernable trends, recreational use attainment on a site-by-site basis is typically around a quarter to a third of the assessed PCR Class A sites and around 15 percent to 30 percent for PCR Class B sites. Interestingly, the attainment rates are consistently higher for the past eight years for the Class A streams compared to the Class B streams, despite the fact that more stringent criteria apply to the Class A streams compared to the Class B streams. PCR Class C and secondary contact recreation sites were excluded from this table due to very limited sample size relative to the Class A and Class B sites.

Table F-13. Annual *E. coli* geometric mean criteria attainment rates by site.

RU ¹	Applicable Geometric								
	Mean Criterion ²	2008	2009	2010	2011	2012	2013	2014	2015
PCR Class A	126 cfu/100 mL	37%	33%	30%	20%	30%	37%	28%	27%
PCR Class B	161 cfu/100 mL	30%	19%	17%	16%	24%	23%	17%	20%

¹ E. coli concentrations are expressed in colony forming units (cfu) per 100 milliliters (mL)

RU Attainment Index Score

Since assessment units can often be composed of monitoring sites having a range of *E. coli* geometric means and the range of impairment can be wide between assessment units, a RU index was developed to provide some differentiation between those assessment units composed of monitoring sites that

greatly exceed the criteria versus those where exceedances are comparably low. The index scores also serve as a useful tool in the TMDL prioritization process (see Section J1.1 for more details). Index scores were only assigned to those assessment units for which sufficient *E. coli* monitoring data were available to assess the RU support as described in Section F2. Index scores range from 0-100 depending on the magnitude of exceedance of the site(s) from the applicable criterion within the AU. An index score of 100 indicates that all sites sampled within the AU fully attained the applicable geometric mean *E. coli* criterion, while lower scores indicate a progressively greater average level of exceedance from the criteria for monitored sites within the AU. Figure F-6 summarizes the index scores for the WAUs. The median WAU index score for the 2016 reporting cycle slipped to 63, slightly lower than the median WAU index score of 70 for the 2014 reporting cycle and very similar to the medians of 63 and 65 for the 2012 and 2010 reporting cycles, respectively.

Figure F-6. Histogram of RU index scores for Ohio's WAUs.

F - 18

The RU attainment status of Ohio's 1,538 WAUs is summarized in Table F-14. This table differs slightly from the summary presented in Table F-12 as this table accounts for those watersheds for which TMDLs have been completed and placed into category 4A and also include historic categorizations carried over from previous reporting cycles.

Table F-14. Summary assessment status of the RU in Ohio's WAUs by Assessment Cycle. See Table J-1 for

assessment category descriptions.

Assessment Category	Number of Assessment Units Categorized				P		f Assessment tegorized	:
	2010	2012	2014	2016	2010	2012	2014	2016
1	59	103	141	153	4%	7%	9%	10%
3	888	673	511	252	58%	44%	33%	16%
4	266	341	425	448	17%	22%	28%	29%
5	325	421	461	685	21%	27%	30%	45%
Total	1,538	1,538	1,538	1,538	100%	100%	100%	100%

There are also 23 large rivers in Ohio, eight of which are further divided into two or more subdivisions for a total of 38 large river assessment units. All of Ohio's large river assessment units are designated for Class A primary contact recreation with the exception of a portion of the Maumee River. Large river assessment units have drainage areas greater than 500 square miles and comprise in total 1,236 river miles in the state. The large river assessment units were analyzed independently of the WAUs through which they flow and LRAU data were not included in WAU assessments. Table F-15 summarizes the results of the analysis of *E. coli* data for the large river assessment units and the resulting RU support determinations and index scores. Sufficient data were available to determine the use support status for 17 of the 38 LRAUs (45 percent) in the 2016 reporting cycle, very similar to 16/38 or 42 percent of the LRAUs in the 2014 reporting cycle. These 17 LRAU subdivisions had an average spatial sampling frequency ranging from 2.9 to 7.6 stream miles. Ohio EPA would need to collect samples from 35 to 49 sites per year on large rivers (minimum of 175 to 245 samples) per year in order to be able to maintain up-to-date RU assessments and index scores for all of the LRAUs within the state.

The LRAU with the greatest sampling intensity in terms of sampling location frequency was the Stillwater River, with an average distance of 2.9 river miles between sampling stations. Of the 17 LRAUs having sufficient data to assess, three (Auglaize River, Sandusky River – Wolf Creek to Sandusky Bay, Scioto River – Paint Creek to Sunfish Creek) fully supported the use while the remaining 14 were not supporting the use. Three of the fourteen non-supporting LRAUs are in fact very close to reaching full attainment, having index scores of 90 or greater. The Little Miami River from O'Bannon Creek to the mouth had the lowest index score (40) followed by the Great Miami River from Fourmile Creek to the mouth (46) of all the index scores calculated for the 17 assessed LRAUs.

Table F-15. Summary assessment status of the RU in Ohio's LRAUs.

F3.3 Inland Lakes

Data availability for inland lakes is relatively limited compared to that for streams and rivers. A total of 519 samples were collected from 46 different lakes in the period 2011-2015. Lakes were typically sampled at an open water location (L-1), with some larger lakes being sampled at multiple open water locations (L-2, L-3). Samples were collected at beach locations too for those lakes having a swimming beach. Samples were also collected at other locations of interest, such as boat ramps, marinas and water supply intakes. As Ohio's inland lakes sampling program has been rejuvenated, there is more assessment data available compared to that reported in recent IR cycles. Still, the sampling effort at Ohio's inland lakes remains relatively small compared to the monitoring resources for streams and rivers. ODNR maintains a sampling program at state park beaches and is described later in this section. Additional details on the inland lakes sampling program can be found in Section I2 of this report and on Ohio EPA's web page at the following address: http://www.epa.ohio.gov/dsw/inland_lakes/index.aspx.

Table F-16 summarizes the assessment results for the RU of inland lakes at selected sample locations. These data were included as part of the assessment of the WAUs, they are reported below to provide an indication of the performance at individual lakes. Geometric means were generally found to be very low both at open water locations and at beach or other locations sampled. Based on the geometric means, the inland lakes sampled in 2011-2015 are attaining the applicable Class A and Bathing Water *E. coli* criteria at nearly all locations sampled, although it is notable that bacteria levels were observed to occasionally spike above the 235 *E. colil* 100 mL water single sample criterion typically used as the threshold for posting a swimming advisory at a beach.

Table F-16. Summary assessment status of the RU for inland lakes, 2011-2015.

^{*}Value exceeds the single sample maximum bathing water criterion of 235 cfu/100mL.

ODNR's Division of Parks and Recreation also conducts routine bacteria sampling of public bathing beaches at inland state park beaches pursuant to Ohio Revised Code sections 1541.032 and 3701.18. Advisory signs are posted whenever notified by the director of the Ohio Department of Health that the bacteria levels in the waters tested present a possible health risk to swimmers. Advisory postings are recommended whenever the *E. coli* density of a water sample exceeds the bathing water single sample maximum of 235 cfu/100 mL. Sampling frequency at the inland state park beaches is generally once every two weeks. This sampling frequency is much less intense compared to sampling frequency at many of the Lake Erie beaches, which is typically four or more days per week.

Table F-17 summarizes the advisory postings from 2011 through 2015 at 68 of the state's inland state park beaches. Beaches at which more than 10 percent of the samples collected over a recreation season exceeded 235 cfu/100 mL (the bathing beach criterion) are highlighted. The inland lake data from ODNR are presented in the IR for informational purposes and not for official use support determinations since the level of data credibility was indeterminate at the publication of this report. Its inclusion here is intended to notify readers of the existence of this sampling program for these popular recreational resources in Ohio and to provide some information as to the relative amount of data and relative water quality conditions with respect to bacteria indicators. Should Ohio EPA affirm the data as level 3 credible data in the future, it will be considered in the process for making official use support determinations.

^{**}Value exceeds the geometric mean bathing water criterion of 126 cfu/100mL.

Table F-17. Swimming advisory postings at Ohio's inland lake public beaches (2011-2015).

^a Indicates the number of advisories posted, based on a measured *E. coli* density exceeding 235 cfu/100 mL, followed by the number of samples collected.

Beaches at inland state park lakes are tested for bacteria less frequently compared to those beaches along Lake Erie. Sampling was most frequent at Alum Creek Lake (2011-2012), Buck Creek Lake-main (2011-2013), Buckeye Lake (2011) and Grand Lake St. Marys (2011). Even at these beaches, the sampling frequency is roughly only half as intense as that of many Lake Erie beaches (Table F-7). The more intensive sampling that had been occurring at these beaches earlier in this reporting cycle tapered off during the later years of this reporting cycle.

The sample results in Table F-17 indicate that at most inland lake beaches, the bacteria criteria are not frequently exceeded, resulting in fewer postings compared to some of the beaches along Lake Erie. There were 45 inland lake beaches where the overall exceedance frequency was less than 10 percent for the five-year reporting period. Overall, the frequency of exceedances for all the inland lake beaches during the five-year reporting period was 12.4 percent, slightly higher than the 10.5 percent reported in the 2008-2012 reporting period. There were 23 inland lake beaches where the aggregated exceedance frequency was over 10 percent. The highest aggregated exceedance frequency of 42 percent was found at the Brooks Park beach at Buckeye Lake. Nine beaches exceeded the bathing water criteria over 25 percent of the time over the five-year reporting period total: Buckeye Lake Brooks Park, Fairfield and Crystal beaches; Grand Lake St. Mary's main beach (west) and Windy Point beaches; Dillon Lake swimmers beach, Caesar Creek (south beach), Madison Lake and Scioto Trail Lake. Sample results at some inland lake beaches indicated a need for posting an advisory much more frequently during certain years. For example, 67 percent of the samples collected during the 2014 recreation season at the Buckeye Lake's Crystal Beach exceeded the applicable single sample bathing water criterion. More frequent sampling, particularly at beaches where previous sampling data indicates an increased

likelihood of exceeding the recreation criteria, should be considered by beach managers so that the public can be adequately informed of actual water quality conditions at the time of their visit.

G

Evaluating Beneficial Use:

Aquatic Life

G1. Background and Rationale

G1.1 Background

Ohio EPA has been evaluating streams using standardized biological field collection methods for nearly 40 years. Stream assessments are based on the experience gained through the collection of well over 26,000 fish population samples, nearly 13,500 macroinvertebrate community samples and close to 210,000 water chemistry samples. Aquatic life use (ALU) assessments for the 2016 Integrated Report (IR) are based on biological and chemical data collected from primarily 2005-2014 at over 4,250 wadeable stream, large river and Lake Erie shoreline sampling locations; some 2003 and 2004 data were included in the large river assessments. Ohio's Credible Data Law states that all data greater than five years in age will be considered historical, but that it can be used as long as the director of Ohio EPA has identified compelling reasons as to why the data are credible. In the case of biological monitoring data, the use of data older than five years is necessary. The use of "historical" data is necessary because not enough biological samples are gathered from enough locations each year to conduct a thorough assessment of ALU status across the state. Owing to limited staff and budget resources, it generally takes ten to fifteen years to visit a sufficient number of assessment units (AUs) and sufficiently monitor them to make ALU assessments. A more complete picture of statewide ALU health is presented when data are utilized based on the 10- to 15-year timeframe. Since water resource quality in many watersheds in Ohio today is most susceptible to changing land use patterns that are often subtle, slow to evolve and difficult to monitor and assess, the use of older data is justified.

Ohio's water quality standards (WQS) have seven subcategories of ALUs for streams and rivers (see Ohio Administrative Code 3745-1-07, http://www.epa.ohio.gov/portals/35/rules/01-07.pdf). The WQS rule contains a narrative for each ALU and the three most commonly assigned ALUs have quantitative, numeric biological criteria that express the minimum acceptable level of biological performance based on three separate biological indices. These indices are the Index of Biotic Integrity (IBI) and Modified Index of Well-Being (Mlwb) for fish and the Invertebrate Community Index (ICI) for aquatic macroinvertebrates. A detailed description of Ohio EPA's biological assessment and biocriteria program including specifics on each index and how each was derived is available (see Biological Criteria for the Protection of Aquatic Life, http://www.epa.ohio.gov/dsw/bioassess/BioCriteriaProtAqLife.aspx).

Procedures established in a specially designed 1983-1984 U.S. EPA study known as the Stream Regionalization Project (Whittier et al. 1987) were used to select reference, or least impacted sites, in each of Ohio's five Level III ecoregions (Omernik 1987). Biological data from a subset of these sites in addition to supplemental data from other least impacted Ohio reference sites were used to establish the ecoregion-specific biocriteria for each ALU. Note that some criteria vary according to stream size and some indices do not apply in certain circumstances. Ohio's WQS rule stipulates that "biological criteria provide a direct measure of attainment of the warmwater habitat, exceptional warmwater habitat and modified warmwater habitat ALUs" [OAC 3745-1-07(A)(6)]. The numeric biological criteria based on IBI, MIwb and ICI thresholds applicable to exceptional warmwater habitat (EWH), warmwater habitat (WWH) and modified warmwater habitat (MWH) waters are found in Table 7-15 of the WQS rule. Neither coldwater habitat (CWH) nor limited resource water (LRW) streams have numeric biological criteria at this time, so attainment status must be determined on a case-by-case basis. For sites and segments designated with these ALUs, attainment status was determined by using biological data attributes (e.g., presence and abundance of coldwater species in CWH streams) and/or interim assessment index targets (e.g., those for LRW streams, Lake Erie lacustuaries, Lake Erie shoreline) to assess consistency with the narrative ALU definitions in the WQS.

G1.2 General Determination of Attainment Status

A biological community at an EWH, WWH or MWH sampling site must achieve the relevant criteria for all three indices or those available and/or applicable, in order to be in full attainment of the designated ALU criteria. Partial attainment is determined if one criterion is not achieved while non-attainment results when all biological scores are less than the criteria or if poor or very poor index scores are measured in either fish or macroinvertebrate communities.

A carefully conceived ambient monitoring approach, using cost-effective indicators consisting of ecological, chemical and toxicological measures, can ensure that all relevant pollution sources are judged objectively on the basis of environmental results. Ohio EPA relies on a tiered approach in attempting to link the results of administrative activities with true environmental measures. This integrated approach includes a hierarchical continuum from administrative to true environmental indicators. The six "levels" of indicators include: 1) actions taken by regulatory agencies (permitting, enforcement, grants); 2) responses by the regulated community (treatment works, pollution prevention); 3) changes in discharged quantities (pollutant loadings); 4) changes in ambient conditions (water quality, habitat); 5) changes in uptake and/or assimilation (tissue contamination, biomarkers, wasteload allocation); and, 6) changes in health, ecology or other effects (ecological condition, pathogens). In this process, the results of administrative activities (levels 1 and 2) can be linked to efforts to improve water quality (levels 3, 4 and 5), which should translate into the environmental "results" (level 6). Thus, the aggregate effect of billions of dollars spent on water pollution control since the early 1970s can now be determined with quantifiable measures of environmental condition.

Superimposed on this hierarchy is the concept of stressor, exposure and response indicators. Stressor indicators generally include activities that have the potential to degrade the aquatic environment, such as pollutant discharges (permitted and unpermitted), land use effects and habitat modifications. Exposure indicators are those that measure the effects of stressors and can include whole effluent toxicity tests, tissue residues and biomarkers, each of which provides evidence of biological exposure to a stressor or bioaccumulative agent. Response indicators are generally composite measures of the cumulative effects of stress and exposure and include the more direct measures of community and population response that are represented here by the biological indices that comprise Ohio's biological criteria. Other response indicators could include target assemblages, i.e., rare, threatened, endangered, special status and declining species or bacterial levels that serve as surrogates for the recreation uses. These indicators represent the essential technical elements for watershed-based management approaches. The key, however, is to use the different indicators within the roles that are most appropriate for each indicator.

Identifying the most probable causes of observed impairments revealed by the biological criteria and linking this with pollution sources involves an interpretation of multiple lines of evidence including water chemistry data, sediment data, habitat data, effluent data, biomonitoring results, land use data and biological response signatures within the biological data themselves. Thus, the assignment of principal causes and sources of impairment represents the association of impairments (defined by response indicators) with stressor and exposure indicators. The identified causes of impairment will serve as the target parameters for future total maximum daily load (TMDL) development or regulatory program actions.

Adequate sampling is necessary to represent the ALU attainment status for large river assessment units (LRAUs, each an average 32 miles in length) or watershed assessment units (WAUs, each an average 28

mi² in surface area); these AUs are defined in Sections D1 and G2 and further detailed in Section J of this report. Despite Ohio EPA's significant commitment to biological sampling efforts, about 36 percent of Ohio's 1538 WAUs are precluded from this analysis because of no or insufficient data or data are considered historical (at least 10 years old). However, most large Ohio rivers with LRAU reaches have current data; however, three major rivers (four LRAUs) are being assessed with data collected just outside the 10-year window. While some data may be available for some of the AUs, many have no water quality monitoring data or the scope of monitoring was judged to be too limited to adequately generate an assessment. Generally, at least two sample sites are minimally considered necessary for a WAU assessment, although under specific circumstances, a WAU may be evaluated with one site. Presently, Ohio EPA prefers that the principal investigators make informed decisions about the data relevance for a particular AU evaluation rather than institute specific guidance on minimum effort.

Recognizing the state's limited resources, one way to increase assessment unit coverage is to utilize all available relevant data. While Ohio EPA uses data from a variety of sources in its work, the data used to determine the ALU status in this report were primarily collected by Ohio EPA. For this report and some past reports, additional biological data were provided by the Ohio Department of Natural Resources (ODNR), Northeast Ohio Regional Sewer District (NEORSD), U.S. Geological Survey (USGS), the University of Toledo, the Ohio State University, National Center for Water Quality Research (NCWQR) at Heidelberg College, Midwest Biodiversity Institute (MBI), Cleveland Metroparks and EnviroScience, Inc. Those interested in providing data to Ohio EPA for ALU attainment status determinations must attend appropriate training provided by Ohio EPA or its designee (e.g., through the Ohio Credible Data Program Level 3 Certification) and document and retain competency in Ohio EPA biological sampling protocols. All data used to make attainment determinations are carefully reviewed for consistency with all Ohio EPA methods and guidance.

G2. Evaluation Method

G2.1 Rivers and Streams: LRAUs

Decades of monitoring work by Ohio EPA have resulted in an extensive data set that includes data for all 38 LRAUs in Ohio with sampling spanning 2003-2014. The longitudinal sampling pattern (upstream to downstream and bracketing pollution sources and tributaries) used to measure fish community health, macroinvertebrate community condition and water chemistry allows WQS biocriteria attainment status to be fairly precisely estimated based on linear distances. The length of the large river deemed to be in full attainment, as described in the previous section, is divided by the total assessed length of the large river and multiplied by 100 to yield a value between 0 (no miles in attainment) and 100 (all miles in attainment). An LRAU is considered meeting its designated ALU only if a score of 100 is reported. In other words, if all miles are not in full attainment of the designated ALU, the entire LRAU is listed as impaired and placed in IR Category 4 or 5, depending on whether a TMDL is required.

G2.2 Rivers and Streams: WAUs

Beginning with the 2010 IR, the ALU assessment methodology defined the WAU as the USGS 12-digit hydrologic unit code watershed or HUC12 (1,538 HUCs averaging 28 mi² drainage areas), rather than the 11-digit HUC watershed (331 HUC11s averaging 130 mi² drainage areas) used in prior IRs. Reporting on the HUC12 scale provides information on a finer scale and allows for better reporting of watershed improvements.

This dramatic reduction in assessment unit size requires consideration of what constitutes adequate sampling within each HUC12 WAU and appropriate evaluation of the sampling results. The relatively small drainage area of the HUC12 WAU requires that the sites evaluated adequately characterize the smaller watershed. For that reason, three scores will be determined for each WAU when sufficient data make this possible. A headwater assessment score that characterizes the aquatic community of the WAU by itself will occur by evaluating all sites with drainage area <20 mi² together. A wading stream score will be determined for all sites with drainage area between 20 mi² and 50 mi² that occur within the WAU. The wading stream score is necessary since a site between 20 mi² and 50 mi² characterizes the entire watershed upstream from the site, potentially two or more HUC12s, not just to the extent of the WAU boundary where the site resides. A principal stream score for sites >50 mi² will also be calculated, as these larger streams reflect a much greater land area than sites at a smaller drainage area. The final assessment unit score will be derived from these three scores. The table below represents this graphically.

WAU (HUC12)	Headw	ater Assess (<20 mi²)			ling Assessn ≥ 20 mi² <50		Intermediate Score (IS)		al Assessmei 0 mi² <500 n		WAU Score
, ,	Total Sites	# Sites Full	HA Score	Total Sites	# Sites Full	WA Score	HA+WA 2	Total Sites	# Sites Full	PA Score	IS+PA 2

While the smaller size of the HUC12 WAU greatly reduces the number of sites necessary to be assessed, this creates an emphasis on appropriate sampling locations within the assessment unit. To ensure that decisions regarding adequate coverage are uniformly carried out, a flow chart for the process was created (Figure G-1). The flow chart takes into account the drainage area associated with a minimal number of sites and incorporates questions as to spatial proximity of the sites within the watershed, land use consistency among sampling locations and location of significant dischargers within the WAU.

Once it is determined that sampling coverage is adequate to conduct a WAU assessment, the number of headwater sites demonstrating full ALU attainment are divided by the total number of headwater sites within the WAU. The quotient is then multiplied by 100 to provide the headwater score.

Determining the wading stream and principal stream scores involve a similar approach. The wading stream score is based on the number of wading stream sites (sites draining a watershed between 20 mi² and 50 mi²) demonstrating full attainment of ALU. The total number of wading stream sites in full attainment are divided by the total number of wading stream sites. The quotient is then multiplied by 100 to provide the wading stream score. The same methodology is used to produce the principal stream score, but the scoring is limited to those sites in the WAU draining >50 mi².

Figure G-1. Flowchart for determining if WAU score can be derived based on available sampling locations.

An intermediate WAU score is calculated as the average of the headwater and wading stream scores. The overall WAU score is derived by averaging the intermediate score and the principal stream score. For HUC12s without principal streams, the intermediate stream score will represent the overall WAU score. This procedure provides some weighting to the assessment when principal stream miles are present (i.e., more influence on the final watershed score by principal streams). This weighting is important in that full use or impairment within the principal streams reflects the overall condition of the much larger primary watershed. A manual scoring adjustment is made in those few instances when a WAU score, with many principal stream sites, is unduly affected by the results from one headwater or one wading site. A WAU meets its aquatic life designated use only if a score of 100 is reported. In other words, if all sites are not in full attainment of the designated ALU, the WAU is listed as impaired and placed in IR Category 4 or 5, depending on whether a TMDL is required.

Additional synthesis of data was used to provide aggregate statewide statistics for Ohio's universe of assessed wading and principal streams and rivers (> 20 mi² drainage areas) and large rivers (> 500 mi² drainage areas). Baseline IR statistics generated beginning with the 2010 IR were used along with the updated 2016 IR results to track trends of attainment levels across Ohio's watersheds and large rivers in an effort to quantify progress made in point and nonpoint source pollution controls and in meeting Ohio's goals of 80 percent full ALU attainment by 2020 for assessed WAU wading and principal stream and river sites and 100 percent full ALU attainment by 2020 for assessed LRAU miles.

G2.3 Lake Erie Shoreline and Islands: Lake Erie Assessment Units (LEAUs)

ALU determinations are predicated on a narrative description of the aquatic community associated with the relevant use tier. In the absence of numeric criteria, the narrative expectation provides the impairment determination. In 1997, Ohio EPA completed the document *Development of Biological* Indices Using Macroinvertebrates in Ohio Nearshore Waters, Harbors, and Lacustuaries of Lake Erie in Order to Evaluate Water Quality (Lake Erie Protection Fund Grant LEPF-06-94, undated draft). In 1999, the document Biological Criteria for the Protection of Aquatic Life: Volume IV: Fish and Macroinvertebrate Indices for Ohio's Lake Erie Nearshore Waters, Harbors, and Lacustuaries was produced (Ohio EPA, undated draft). Also in 1999, the document Biological Monitoring and an Index of Biotic Integrity for Lake Erie's Nearshore Waters (Thoma, 1999) was published as a book chapter in Assessing the Sustainability and Biological Integrity of Water Resources Using Fish Communities (Simon, editor, 1999). The data analyses in these documents, including refinement of field sampling protocols and development of assessment indices, provide a foundation to establish numeric biological targets/expectations using IBI and MIwb scores for ALU in Lake Erie along the Ohio shoreline and in lacustuary areas. The term "lacustuary" was coined to specify the zone where Lake Erie water levels have intruded into tributary river channels. The ALU status of a lacustuary is included as part of the assessment of the tributary WAU or LRAU.

Excluding lacustuaries, the status of the Lake Erie shoreline and islands is currently evaluated using fish community assessment targets for the Lake Erie IBI and MIwb based on night electrofishing at sites included in the three LEAUs: Lake Erie Western Basin Shoreline (including Maumee Bay and Sandusky Bay), Lake Erie Central Basin Shoreline and Lake Erie Islands Shoreline. All available fish data were collected from areas within 100 meters of the mainland, bay or island shoreline. Status of LEAUs was determined by the percentage of sites in narrative full attainment of biological targets (scaled to prevailing shoreline habitat type) and where sufficient and current biosurvey data were available.

Ohio EPA was awarded a Great Lakes Restoration Initiative (GLRI) grant in 2010 to develop a comprehensive Lake Erie nearshore monitoring program. This 2011-2013 project included a strategy to design and implement a monitoring program for the Ohio Lake Erie nearshore zone (including bays, harbors and lacustuaries) that can be maintained on an annual basis. It is anticipated that future IRs will include revised AUs and an updated assessment methodology for the LEAUs based on the results of the GLRI study (For a preview of anticipated revisions, see Section I5 of the 2014 IR).

The GLRI grant was a collaborative effort between state agencies (Ohio EPA and ODNR) and major universities with Lake Erie basin research interests and expertise (the Ohio State University, University of Toledo, John Carroll University and Heidelberg University). Physical, chemical and biological parameters monitored from 2011-2013 provided data to support long-term trend analysis, establish background conditions in selected areas and conduct sampling related to the impacts of projects implemented in tributaries of the Lake Erie watershed. Data will be used to monitor the progress of implementation projects in Areas of Concern (AOCs) to restore beneficial uses, track implementation of WAPs, develop TMDLs for pollutants impairing beneficial uses, support Balanced Growth Initiative actions on the shoreline and provide updated information for IRs, Lake Erie quality index updates and updates to the Lake Erie Lakewide Management Plan (LAMP). More information about the GLRI and projects which have been proposed can be found at the Ohio Lake Erie Commission web site (see GLRI, http://www.lakeerie.ohio.gov/GLRI.aspx).

For field years 2016 and 2017, Ohio EPA is utilizing a federal fiscal year 2014 Clean Water Act (CWA) Section 106 Supplemental Monitoring grant to continue funding the base monitoring program conducted by Ohio EPA at shoreline, nearshore and open water sites in Lake Erie. Details of the monitoring program are provided in the current year study plan available at the following web site: http://epa.ohio.gov/dsw/lakeerie/index.aspx#125073721-nearshore-monitoring.

Of note, future Lake Erie assessments will be the collection of shoreline data for the National Aquatic Resource Survey (NARS) of coastal waters of the United States (the National Coastal Condition Assessment - NCCA), which was conducted during the summer of 2015. Coordinated by U.S. EPA in collaboration with Great Lake states, these one-visit snapshots of lake water quality will be used to provide statistically valid national and regional assessments of Great Lakes resource condition. Additional information and 2010 NCCA results, when available, can be found at the U.S. EPA NARS website (see National Aquatic Resource Surveys, http://www.epa.gov/OWOW/monitoring/nationalsurveys.html).

G3. Results

For the 2016 IR, new aquatic life data collected in 2013 and 2014 were incorporated into the assessment database. During this period, biosurvey data from nearly 850 sampling sites located in 226 HUC12 WAUs, 56 sampling sites located in five LRAUs and 21 samples collected from the three LEAUs were available to completely or partially update previously assessed AUs or provide new assessments for AUs with unknown aquatic life status. All data were collected by the Ohio EPA or Level 3 Qualified Data Collector external sources. Watersheds intensively monitored during 2013 and 2014 included the lower Mahoning River, Bokes Creek, lower Muskingum River tributaries, Stillwater River, St. Joseph River, Tiffin River, lower Auglaize River tributaries, Rocky River, Wills Creek, Southwest Ohio River tributaries and Big Darby Creek basins. Large rivers intensively sampled included the Mahoning River, Cuyahoga River,

¹ The federal fiscal year (FFY) is from October 1 to September 30.

Wills Creek, Stillwater River and Tiffin River. Detailed watershed survey reports for many of the basins mentioned above are or will be available from the Ohio EPA Division of Surface Water (see Biological and Water Quality Report Index, http://www.epa.ohio.gov/dsw/document_index/psdindx.aspx).

A further examination of individual AUs was made to determine status changes caused by site data collected during 2003 and 2004 that now exceed the 10-year data threshold and have become "historical" since the 2014 IR. From this examination, it was determined that data from 119 HUC12 WAUs were now insufficient to provide adequate spatial coverage either due to (1) all data being age restricted or (2) enough of the data are age restricted that the number of sites fell below the minimum needed to assess. These AUs are not being delisted if currently Category 5. Significant basins affected, along with last sampling year, include the Olentangy River (2003), Toussaint Creek (2003), Wakatomika Creek (2003), Mad River (2003), lower Grand River (2004) and Hocking River (2004), as well as numerous WAUs in the Tuscarawas River basin assessed in 2003 and 2004. Four LRAUs (Grand River, Hocking River [2] and Mad River) were last sampled in 2003 and/or 2004. However, as these three large rivers were not expected to have changed significantly since the previous sampling, the data is being retained and used in the overall assessment of the large river data.

Summarized 2016 IR statistics for aquatic life assessments for large river, watershed and Lake Erie AUs as well as the comparable statistics from the 2002-2014 IRs are tabulated in Table G-1. More detailed ALU results and statistics for each 2016 AU (watershed, large river and Lake Erie units) with current data are provided at Ohio EPA web pages which can be accessed at http://epa.ohio.gov/dsw/tmdl/OhioIntegratedReport.aspx.

G3.1 LRAUs

LRAUs in Ohio (38 LRAUs spanning 23 rivers with watersheds in excess of 500 square miles and totaling 1,248 river miles) reflected a small decline in percent of monitored miles in full attainment compared to the same statistic reported in the 2014 IR (Table G-1, Figure G-2). Based on monitoring through 2014, the full attainment statistic now stands at 87.4 percent (1063 of 1216 assessed LRAU miles), down 1.8 percent from the 2014 IR. It should also be noted that there was at least one site in 20 of the 38 LRAUs that was not fully supporting the ALU, so those 20 LRAUs are considered impaired (Table G-4).

Significant large rivers assessed during 2013 and 2014 included the Mahoning River (2013), Tiffin River (2013), Stillwater River (2013), Wills Creek (2014) and Cuyahoga River (2014). Attainment statistics for these five rivers (5 LRAUs) are as follows:

- Mahoning River: 45 percent full attainment over 35 miles
- Tiffin River: 100 percent full attainment over 20 miles
- Stillwater River: 95 percent full attainment over 32 miles
- Wills Creek: 55 percent full attainment over 44 miles
- Cuyahoga River: 69 percent full attainment over 24 miles

While both the Stillwater River and Cuyahoga River have had fairly recent assessments prior to 2013 and 2014, respectively and neither reflected significant change, assessments of the other three rivers documented important positive change since their first comprehensive monitoring in the early 1990s, as follows:

- Mahoning River (1994): 0 percent full attainment over 35 miles
- Tiffin River (1992): 0 percent full attainment over 20 miles
- Wills Creek (1994): 16 percent full attainment over 44 miles

In spite of these three rivers showing substantial improvement in ALU attainment based on the most recent monitoring and assessment, the overall 1.8 percent decline in total LRAU miles in full attainment between the 2014 IR and 2016 IR was due to fact that, collectively, the percentage of miles in full attainment for the Mahoning and Wills AUs stands at only 50 percent. These LRAUs were reported with historical data status in past IRs and, thus, were not included in attainment statistics.

Progress towards the "100 percent by 2020" ALU goal for Ohio's large rivers is depicted in Figure G-2. Between the 2002 and 2016 reporting cycles, the percentage of large river miles in full attainment has increased from 62.5 percent to 87.4 percent and, for the first time, nearly 100 percent of total miles have been assessed. Continued success in approaching the 100 percent full attainment threshold for 100 percent of large river miles by 2020 will be dependent on sustained resources allocated to monitoring LRAUs with an emphasis on those which are likely to become historical between now and 2018 (the last year of data to be included in the 2020 goal assessment) and which are currently not scheduled to be resampled before then (8 large rivers/10 AUs representing nearly 310 large river miles).

G3.2 WAUs

For the 2016 IR, the average HUC12 watershed assessment unit (WAU) score reflected a positive increase from the corresponding score reported in the 2014 IR (Table G-1, Figure G-3). Based on monitoring through 2014, the average HUC12 WAU score stands at 61.5, a 2.3 point increase from the 2014 IR and typical of what has been observed over the last several cycles (a pattern of steady increases of 1-2 points). Included in Table G-1 and depicted in Figure G-3 is the corresponding average score based on the old HUC11 WAUs, which were tracked from 2002 through 2010 and were used to gauge the progress of the "80 by 2010" ALU goal as reported in the 2010 IR.

Table G-2 depicts the breakdown of site full attainment based on the watershed size category used to determine an individual watershed's score based on available sites in the HUC12 WAU. As in previous reports, the results show that biological impairment is more likely at sites on small streams (nearly 1 in 2 headwater sites are impaired) and that impairment lessens significantly as sites drain larger areas (nearly 7 in 10 principal stream and small river sites are in full attainment). This phenomenon correlates well with the most widespread causes associated with aquatic life impairment in these watersheds.

Table G-3 and Figure G-4 depict the attainment status breakdown of the 3875 WAU sites collected from 2005-2014 by designated or recommended (existing) ALU. As would be expected, most sites (72 percent) are assigned the base warmwater habitat (WWH) ALU, for which attainment of biocriteria signifies meeting the fishable/swimmable goal of the Clean Water Act (CWA). For this cycle, about 53 percent of assigned WWH sites are meeting the WWH use. About 20 percent of the 3875 sites are assigned more protective ALUs (exceptional warmwater habitat-EWH, coldwater habitat-CWH or a dual use which includes both-EWH/CWH). The remaining sites (8 percent) are assigned "less than goal" CWA uses (MWH and LRW). Both more protective and "less than goal" uses are only assigned after a use attainability analysis has been conducted based on rigorous field data and this study determines that the assigned ALU is the most appropriate to protect existing high quality/unique biological communities or set reasonable restoration benchmarks for communities challenged by pervasive anthropogenic or natural influences. As might be expected, a high percentage of sites assigned to more protective uses

are fully meeting that use (84 percent) while those with assigned "less than goal" uses have low achievement of even the lower expectations of these uses (57 percent meet).

Table G-4 lists the top five ALU impairment causes for the period 2003 through 2014. For this time period, principal causes for HUC12 WAU impairments were those primarily related to landscape modification issues involving agricultural land use and urban development. These types of impairments would be most manifest in smaller streams, a fact backed up by the numbers presented in Table G-2. It is important to note that between 24 percent and 48 percent of impaired HUC12 WAUs had at least one monitored site impaired by one of these individual causes and many WAUs had several sites affected by three or more of the five causes listed as responsible for the ALU impairment. This would not be an unusual situation given the frequently close association between these impairment causes (e.g., nutrients, sedimentation/siltation, habitat modifications and hydromodifications in rural/agricultural landscapes relying on channelization and field tiles for drainage). Also of note is the prevalence of HUC12 WAUs and LRAUs which are impaired by the generic organic enrichment cause category; 30 percent of impaired WAUs show "sewage" related impairments such as high biochemical oxygen demand, elevated ammonia concentrations and/or in-stream sewage solids deposition. Eight of 20 impaired LRAUs also note sewage related causes. While the WAU percentage is not as high as reported in the 2014 IR, it is still comparable to those percentages reported in past IRs that tracked these cause statistics, which suggests that adequate treatment and disposal of human and animal wastes via wastewater treatment plants, home sewage treatment systems and land applications of septage and animal manure continue to be critical water quality issues in many Ohio watersheds.

Progress towards the "80 percent by 2020" ALU goal for Ohio's wading and principal stream and river sites (those monitored sites draining watersheds between 20 and 500 square miles) is depicted in Figure G-5. Contrasted with the 2010 IR statistic, when the 2020 goal benchmark was established, the percentage of qualifying sites in full attainment has increased nearly five percentage points with an increase from 61.4 percent to 66.1 percent. If this rate of change remains consistent over the next four years (*i.e.*, with new data collected through 2018), the statistic will approach 70 percent but will not reach the goal by the time the 2020 IR is produced. It is readily apparent that more proactive implementation of watershed recommendations in TMDL reports and watershed action plans (WAPs) will be needed to recover impaired aquatic communities and protect those currently meeting aquatic life expectations in order to meet the 80 percent goal. It will also be critical that resources be directed to follow-up monitoring in areas with implemented restoration and protection projects so that success of efforts can be documented and reflected in future goal statistics. This latter effort is now well underway in survey areas with TMDLs approved and implemented beginning in the late 1990s and is an ongoing activity in support of the Ohio EPA Nonpoint Source Program (see http://epa.ohio.gov/dsw/nps/index.aspx for more program information).

G3.3 Lake Erie Assessment Units (LEAUs)

For previous IRs, assessments were based on past data collected in the mid-1990s through the early 2000s. Significant changes appear to be ongoing in Lake Erie and, as a result, these older data are no longer being used to determine ALU attainment status in the three LEAUs. However, these data are used in the following discussion to highlight key trends in fish community condition over two time periods of sampling.

From 2011-2014, 116 fish community collections using night electrofishing methods (day electrofishing at two Sandusky Bay sites) were taken from 45 sites spread over the three LEAUs and these data serve

as the core data set for assessment of Lake Erie shoreline status. For this cycle, and despite the rather limited amount of data, the assessment methodology as used in past IRs was once again used to determine ALU status in the LEAUs. This included the average IBI and MIwb scores for all sampling passes available at a given sampling location which were then compared to target expectations based on the prevailing bottom substrate type at that location (hard bottoms, *e.g.*, bedrock, boulder, rubble or soft bottoms, *e.g.*, sand, silt, muck). Results for the IBI and MIwb scores at 31 shoreline sites (excluding Sandusky Bay and the Lake Erie Islands sites) compared to expectations are presented in Figures G-6 and G-7.

All three LEAUs remain Category 5 with significant impairment of sites due primarily to tributary loadings of nutrients and sediment, exacerbated by continued trophic disruptions caused by the proliferation of exotic species, algal blooms and shoreline habitat modifications. In the aggregate, only six fish community collections were assessed as fully attaining the designated EWH ALU; 14 were assessed as partially attaining and the remaining 25 were in non-attainment (Table G-1). With the exception of attainment results reported for the 2012 IR, when the size of the database was severely restricted, the percentages of sites in full attainment of the EWH ALU have not changed significantly through the IR cycles. One positive may be the increased percentage of sites in partial attainment, at the expense of non-attainment, for the last few cycles when compared to previous earlier cycles. All partial attainment sites were due to Mlwb scores meeting expectations which may reflect better aggregated numerical abundance of fish, increased biomass and structural evenness, the latter being a product of species richness and the distribution of numbers and biomass among the various species.

A breakdown of results reflects the following site attainment status for each of the three LEAUs:

LEAU Name	# Sites	# Full	# Partial	# Non
Western Basin Shoreline (incl. Maumee and Sandusky bays)	19	5	7	7
Central Basin Shoreline	22	1	6	15
Lake Erie Islands Shoreline	4	0	1	3

Three of the six sites, with fish communities meeting ALU target expectations, were collected from Sandusky Bay with two full attainment sites collected from the western basin shoreline along the eastern extent of Maumee Bay (between Immergrun and Cedar Point) and one full attainment site along the West Harbor shoreline just to the west of the Cuyahoga River in Cleveland. At several partial attainment sites where MIwb scores were exceeding target expectations, IBI scores, while not quite meeting targets, were approaching acceptable scores. These shoreline locations were located in Sandusky Bay and near the Grand River, Ashtabula River and Conneaut Creek along Ohio's eastern end of the Central Basin.

For this IR, an attempt was made to compare the recent data set collected 2011-2014 to similar electrofishing results collected from co-located sites sampled in the 1990s and early 2000s. Resulting comparisons of Lake Erie IBI and MIwb scores by individual sampling passes at 45 sites and matching historical sites are presented in Figures G-8 and G-9. For the most part, there seemed to be little change in medians and ranges of these two indices at the sites spanning the two timeframes. The biggest changes appeared linked to Islands Shoreline sites but that may be more an artifact of the small sample sizes. One Lake Erie IBI component metric which did seem to reflect a significant change across the two timespans was the proportion of exotic species by numerical abundance in each sampling pass (Figure

G-10). For Lake Erie, typical common exotic species which can be collected using the electrofishing sampling method include round and tube nose goby, white perch, ghost shiner, gizzard shad, common carp and goldfish. Initial assessment of 2011-2014 results implicates large populations of white perch and gizzard shad as the culprits causing the proportional increases in exotic species collected when compared to earlier collections.

Table G-1. Summary of ALU assessment for Ohio's WAUs², LRAUs and LEAUs: 2002-2016 IR cycles.

Section

Evaluating Beneficial Use: Public Drinking Water Supply

Case: 3:17-cv-01514-JGC Doc #: 1-12 Filed: 07/18/17 210 of 601. PageID #: 1207

H1. Background

The 2016 Integrated Report (IR) is the fifth reporting cycle to include assessment of the public drinking water supply (PDWS) beneficial use. Ohio continues to look for connections between Clean Water Act and Safe Drinking Water Act (SDWA) activities and leverage the programs to clean up and protect drinking water sources. Acknowledgement of the public water supply use and identification of impaired waters provides an effective issue in which to engage the public and stakeholders in watershed-wide planning and implementation activities. Conversely, the public water systems can be effective partners in these efforts and stand to benefit through reduced treatment costs, reduced risk to human health and credits toward achieving compliance with new SDWA regulations via source water controls in the watershed.

Assessments for each public water system were completed for nitrate, pesticide and algae (cyanotoxin) indicators. Assessments included in this cycle are based primarily on treated water quality data and to a limited extent other source water quality data available from Ohio EPA and external sources. Information used to complete assessment determinations include public water system treatment information, intake location, number and type of reservoirs and water quality data. Assessments were completed for stream sources, in-stream impounded reservoir sources and upground reservoirs with active drinking water intakes. Figure H-1 identifies Ohio watershed assessment units (WAUs) and large river assessment units (LRAUs) that contain surface waters currently utilized as drinking water sources by a public water system. WAUs correspond to 12-digit hydrologic unit codes. Three public water systems had intakes go inactive since the last reporting period, including MWCD-Atwood Park (Atwood Lake Intake); Cadiz (Sparrow Reservoir Intake); and Fremont (Sandusky River No. 2 Intake). The WAUs associated with Fremont and MWCD-Atwood Park utilize other active intakes and are assessed in the 2016 reporting period. The WAU associated with Cadiz (Sparrow reservoir intake) was not assessed.

Figure H-1. Ohio WAUs and LRAUs that contain at least one active surface water drinking water intake.

H2. Evaluation Method

The methodology for assessing the PDWS beneficial use was first presented in the 2006 Integrated Water Quality Monitoring and Assessment Report. Updates to the methodology were included in subsequent IRs. The methodology used for this reporting cycle, including the use of an algae indicator, is described in this section. For more detail on how the method was first developed and rationale for indicator selection and exclusion, please refer to the initial methodology at http://www.epa.ohio.gov/portals/35/tmdl/2006IntReport/IR06 app C PDWSmethodology.pdf.

H2.1 Beneficial Use Designation

The PDWS use designation is defined in paragraph (B)(3) of OAC rule 3745-1-07. It applies to public waters that, with conventional treatment, will be suitable for human intake and meet federal regulations for drinking water. Although not necessarily included in rules 3745-1-08 to 3745-1-30 of the Ohio Administrative Code, the bodies of water with one or more of the following characteristics are designated public water supply by definition:

- All publicly owned lakes and reservoirs, with the exception of Piedmont reservoir;
- All privately owned lakes and reservoirs used as a source of public drinking water;
- All surface waters within 500 yards of an existing public water supply surface water intake; and
- All surface waters used as emergency water supplies.

Ohio EPA is focusing assessment efforts and limited resources on water bodies currently serving as public drinking water sources. Water bodies with inactive drinking water intakes that are being maintained as an emergency source of drinking water will also be assessed. Assessments for waters designated with the PDWS use but not currently used as a drinking water source are considered a lower priority and will likely be assessed only when water quality data is available.

Attainment determinations will apply to hydrologic assessment units (AUs) as defined by Ohio EPA's Division of Surface Water (DSW). For inland rivers the assessment unit is defined as the 12-digit hydrologic unit code (HUC 12) or the large river assessment unit. Lake Erie beneficial use assessments apply to the corresponding Lake Erie shoreline assessment unit. Although this beneficial use designation applies to a 500-yard zone surrounding the intakes, the attainment determination will be associated with the corresponding hydrologic assessment unit and factor into the 303(d) priority listing determination for impaired waters.

H2.2 Water Quality Standards

Water quality standards are designed to protect source water quality to the extent that public water systems can meet the finished water SDWA standards utilizing only conventional treatment. Source water quality will be assessed though comparison of in-stream and applicable treated water quality data to numeric chemical water quality criteria for the core indicators: nitrate; pesticides and other contaminants; and *Cryptosporidium* (following criteria development). The numeric water quality criteria correspond to the maximum contaminant levels established by the SDWA or were adopted from U.S. EPA's 304(a) recommended water quality criteria. Criteria will apply as average concentrations except for nitrate. At elevated levels, nitrate can cause acute health effects and the SDWA finished water standard applies as a maximum concentration not to be exceeded. Consequently, the water quality

criteria for nitrate will be applied as a maximum value. Annual time-weighted mean pesticide concentrations were calculated by taking the annual average of the quarterly averages and comparing to the water quality criteria.

An additional core indicator based on algae and associated cyanotoxins was incorporated into the assessment methodology for the 2014 IR. It is based on the aesthetic narrative criteria for algae described in OAC rule 3745-1-07 and uses cyanotoxins as an indicator of algae impairment. The State of Ohio developed numeric cyanotoxin drinking water thresholds for microcystins, saxitoxins, anatoxin-a and cylindrospermopsin in 2011 (See 2014 *State of Ohio Public Water System Harmful Algal Bloom Response Strategy* available at

http://www.epa.ohio.gov/Portals/28/documents/PWS HAB Response Strategy 5-30-12.pdf). These thresholds are the basis for all cyanotoxin indicators of impairment. In 2015, U.S. EPA released Health Advisory concentrations for microcystins and cylindrospermopsin, which Ohio EPA adopted in the 2015 State of Ohio Public Water System Harmful Algal Bloom Response Strategy. In 2016, Ohio EPA adopted the U.S. EPA Health Advisories for microcystins and established microcystins monitoring and reporting requirements in rule. Ohio EPA plans on reviewing the algae impairment assessment methodology prior to the next reporting cycle to determine potential incorporation of U.S. EPA's cyanotoxin health advisories and revisions to the indicators of impairment. Since cyanotoxin thresholds are based on acute or short-term exposures, the criteria are based on a maximum concentration not to be exceeded. Cyanotoxins have been detected in sources of drinking water since 2009, but were not detected above drinking water thresholds in finished water until 2013. Finished water detections at Carroll Township in 2013 and at Toledo in 2014 led to the issuance of "Do Not Drink" advisories due to cyanotoxins. The Toledo advisory affected almost half a million people and underscores the need for PDWS use assessments to consider algae impacts. Possible future algae indicators include: Total Trihalomethanes (TTHMs) or Haloacetic Acids (HAA5) MCL violations; elevated total organic carbon (TOC); taste and odor events; and additional treatment or source control requirements associated with algae impacts.

H2.3 Attainment Determination

Each assessment will result in identification of one of three attainment categories: Impaired, Full Attainment and Not Assessed-Insufficient Data. For AUs with multiple PDWS zones, the attainment statuses of all zones are combined and the lowest attainment status applied to determine the PDWS assessment status for the entire assessment unit. That is, the overall AU status is considered "Impaired" if any of the PDWS zones have an impaired attainment status. Conversely, the overall assessment status for the AU could be listed as "Full Support" only if sufficient data for at least the nitrate indicator was available to determine the attainment status for all PDWS zones within the AU.

The following table displays some potential scenarios that might occur within an assessment unit, either with one PDWS zone or multiple zones. In each case, the reverse situation of what is shown might occur (e.g., for the first row, full support of the first indicator and insufficient data for the second indicator would result in an AU assessment status of insufficient data).

Nitrate Indicator	Pesticide or Other Indicator	AU Assessment Status
Full support	Full support/Insufficient data	Full support
Full support	Impaired	Impaired
Impaired	Insufficient data/Full Support	Impaired
Insufficient data	Impaired	Impaired
Insufficient data	Insufficient data/Full Support	Insufficient data

AUs are further evaluated for water quality conditions placing them on a "watch list." Source waters are placed on the "watch list" where water quality was impacted, but not at a level that indicates impairment. Waters may remain on the watch list based on historical data, if current raw water data or applicable finished water quality data are not available. While these waters are still considered in full attainment of the PDWS use, they will be targeted for additional monitoring and more frequent assessment, if resources are available. Table H-1 identifies impaired and "watch list" water quality conditions.

Table H-1. PDWS attainment determination.

Applies to ambient and treated water quality data from 2010 through December 2015.

Indicator	Impaired Conditions
Nitrate	☐ Two or more excursions ^a above 10.0 mg/L within the 5-year period
Pesticides	☐ Annual average exceeds WQ criteria (atrazine = 3.0 μg/L)
Other Contaminants	☐ Annual average exceeds WQ criteria
Algae: Cyanotoxins ^b	☐ Two or more excursions ^a above the state drinking water thresholds (microcystins = 1.0 μg/L) within the 5-year period
Cryptosporidium ^c	☐ Annual average exceeds WQ criterion (1.0 oocysts/L)
Indicator	Full Attainment Conditions
Nitrate	☐ No more than one excursion ^a above 10.0 mg/L within the 5-year period
Pesticides	☐ Annual average does not exceed the WQ criteria (atrazine = 3.0 μg/L)
Other Contaminants	☐ Annual average does not exceed the WQ criteria
Algae: Cyanotoxins	\square No more than one excursion above the state drinking water thresholds (microcystins = 1.0 μ g/L) within the 5-year period
Cryptosporidium	☐ Annual average does not exceed the WQ criterion
Indicator	"Watch List" Conditions Source waters targeted for additional monitoring and assessment
Nitrate	☐ Maximum instantaneous value > 8 mg/L (80% of WQ criterion)
Pesticides	 □ Running quarterly average ≥ WQ criteria □ Maximum instantaneous value ≥ 4x WQ criteria
Other Contaminants	☐ Maximum instantaneous value ≥ WQ criteria
Algae: Cyanotoxins	\square Maximum instantaneous value \ge 50% of the state drinking water thresholds
Cryptosporidium	☐ Annual average ≥ 0.075 oocysts/L

^a Excursions must be at least 30 days apart in order to capture separate or extended source water quality events.

b Impaired conditions based on source water detections at inland public water systems and detections at public water system intakes for Lake Erie source waters. Cyanotoxins include: microcystins, saxitoxins, anatoxin-a and cylindrospermopsin.

^c Impaired conditions for *Cryptosporidium* are based on water quality criteria that Ohio EPA intends to develop.

¹ Impaired waters may also be on a watch list for an indicator for which they are not impaired. For instance, the Beaver Creek watershed (04100011-12-02) is impaired for algae, but is on the watch list for nitrates.

H2.4 Data Sources and Requirements

In order to capture current water quality conditions, these assessments have traditionally focused on the most recent five years of data. However, for the 2016 IR, the eligible data timeframe for this beneficial use only was expanded to incorporate the most recent six years of data and include the 2015 results. The 2016 PDWS use impairment list was developed using public water system compliance monitoring treated data and ambient water quality data from January 2010 through December 2015. Water quality data were requested and obtained from the Syngenta Crop Protection, Inc. Atrazine Monitoring Program (AMP; 2010-2014). Treated water quality data were obtained from the Safe Drinking Water Information System (SDWIS) database, which contains all SDWA compliance data submitted to the Division of Drinking and Ground Waters (DDAGW) by Ohio public water systems and their certified laboratories. Raw water quality data from samples collected near intakes were obtained from the DSW's ambient monitoring database and level 3 credible data collected and submitted by level 3 qualified data collectors. Additional raw water quality data were collected by DDAGW at intake locations within DSW watershed surveys. Cyanotoxin data were retrieved from Ohio EPA's Harmful Algal Bloom database.

Treated water quality data could only be used for the assessments if the water system did not blend with ground water, selectively pump from the stream source to an upground reservoir to avoid contamination, or use a nitrate or pesticide removal treatment process. A significant number of water systems use activated carbon during the water treatment process, which precludes use of the treated pesticide data for PDWS assessments and leads to a significant number of assessments completed with nitrate data only.

To assure that surface water samples are representative of the source water, the following sampling guidance was followed:

- Preferred sampling location was within the 500-yard PDWS zone or directly at the intake.
 Samples collected at the treatment plant raw water line were also considered representative;
- Data collected upstream from the intake beyond the 500-yard zone were utilized if there were
 no significant hydrologic or water quality changes between the sample location and the intake.
 Dams, channel modification, tributaries with significant flow or contaminant sources were
 assumed to significantly alter in-stream water quality and limit applicability of farther upstream
 sampling data;
- For PDWS lakes and reservoirs with known stratification or seasonal turnover, the preferred data collection location was either the raw water intake line or in the lake at the same depth or zone as the raw water intake screen(s). Surface sampling data collected at the intake were utilized if no other raw water data were available.

PDWS attainment determinations based on small sample sets present several challenges. The small sample set may fail to identify an exceedance of a water quality standard, resulting in a determination of attainment when in fact an area is impaired. Statistical confidence in the determination decision is also reduced. To address these concerns, the assessment looks at multiple lines of evidence including several sources of water quality data and treatment plant information. The attainment decision target sample size is 20 samples collected within the past five years. This sample count will provide sufficient power to detect exceedances of greater than or equal to 15 percent above the criterion with a Type I error of 0.15. Ohio EPA has limited resources for source water sampling, therefore attainment determinations may be concluded with a minimum of 10 samples if these samples represent the critical

period when the contaminant is typically detected. Attainment decisions may also be made with less than the required sample count when there is overwhelming evidence of impairment, such as a large single sample exceedance of nitrate or microcystins (verified with a repeat sample).

Many source water contaminants occur in surface waters seasonally with maximum concentration in early spring through summer. In order to assure that sampling for nitrates and pesticides accurately characterizes these seasonal fluxes, at least 50 percent of the samples are collected from the period March to August with at least two years represented. The critical sampling time for cyanotoxins is late spring through fall (May to November). In order to minimize dataset seasonal bias, any impairment determination based on exceedance of a mean water quality criterion requires a minimum of 10 samples representing at least two seasons. If a large dataset is available with sample collection skewed toward high flow events (i.e., stratified sampling program), it may be necessary to calculate time-weighted seasonal or monthly average values.

Most of the nitrate assessments were completed with sufficient samples and well over the recommended minimum sample counts. Much lower sample counts for pesticides were available and several assessments were completed with fewer than 10 samples. Use of fewer than 10 samples was allowed if the samples were collected from at least two separate years, the samples were all within the spring runoff period (typically March through June) and all results were well below (all results less than 50 percent) the water quality criteria. Exception to the ten sample minimum was also allowed if the PDWS zone was in an area with minimal atrazine application, all samples were also below the criteria and available samples were collected during the spring runoff period when occurrence is most likely.

To provide additional information within the "Not Assessed" reporting category 3, "i" was added to note when some water quality data were available but not enough to complete an assessment. A determination was also made to retain all impaired listings until sufficient valid data were obtained to justify delisting.

The impaired status will remain until there are five consecutive years without any excursions and sufficient raw water data are obtained. The same number of samples required to list an AU as impaired due to nitrate, pesticides or algae will be required to delist the AU.

For the 2016 assessment cycle, only the nitrate, pesticide and algae (cyanotoxin) indicators were evaluated in-depth. Other contaminants monitored by the public water systems for SDWA compliance and reported in the SDWIS database were also reviewed but no in-stream raw water data were evaluated for these contaminants. All available *Cryptosporidium* data from SDWA compliance monitoring were reviewed for this assessment cycle, but the water quality criteria have not yet been established and no impairment determinations could be made based on this parameter.

H2.5 Ohio River Assessments

The Ohio River Valley Water Sanitation Commission (ORSANCO) evaluates the PDWS use for Ohio River intakes and present assessments in the Biennial Assessment of Ohio River Water Quality Conditions Report. ORSANCO is an interstate agency that was created in 1948 to control and abate pollution in the Ohio River Basin. ORSANCO operates programs to monitor, assess and improve water quality within the basin. Consequently, Ohio EPA will not assess the PDWS use for intakes located on the Ohio River. ORSANCO's water quality standards are available at the commission's website: http://www.orsanco.org.

H3. Results

Using the PDWS assessment methodology and available water quality data, results for the PDWS beneficial use are presented here for all WAUs, LRAUs and Lake Erie AUs (LEAUs) where the PDWS use applies. Applicable water quality data were evaluated to determine an impairment status for each key indicator in each AU. In order to be considered "assessed," sufficient data were required for only the nitrate indicator. There are a total of 119 public water systems using surface water (excluding Ohio River intakes) in 123 separate AUs. The 123 AUs with the PDWS beneficial use include the following: 111 WAUs, nine LRAUs and all three LEAUs. A summary of the nitrate, pesticide and algae (cyanotoxin) indicators for each public water system are presented in Section H4. Table H-2 provides supporting information for each of the 29 AUs listed as impaired for the PDWS beneficial use.

Nitrate Indicator. Sufficient data were available to complete nitrate evaluations for 53 (43 percent) of the 123 AUs using data primarily from Ohio EPA's compliance database and Ohio EPA watershed surveys. Of all 123 AUs, five (4 percent) were identified as impaired and 48 (39 percent) were in full support. Impairments included four of the nine LRAUs. Three Maumee River and one Sandusky River LRAU remain impaired. Most of the 27 waters placed on the nitrate watch list (single detection greater than eight mg/L) are located in the northwest part of the state (Figure H-2).

Ohio EPA is working with U.S. EPA to develop a total maximum daily load (TMDL) report that addresses nitrate impacts to all three of the PDWS impaired Maumee River LRAUs. The Maumee River is the source water for five public water supplies.

Pesticide Indicator. Sufficient data were available to complete atrazine evaluations for 26 (21 percent) of the 123 PDWS AUs using data from Ohio EPA's compliance database (treated water), Ohio EPA water quality surveys and Syngenta Crop Protection, Inc.'s AMP. Five of the WAUs were impaired while the remaining 19 were in full support. For LRAUs, five remained on the watch list from the previous report cycle. A total of 24 waters were placed on the pesticide watch list because of elevated atrazine [single exceedance of four times the water quality criteria (WQC) or quarterly average greater than WQC]. These areas of elevated atrazine coincide with the predominantly agricultural land use in western and northwestern Ohio (Figure H-3).

In response to the atrazine drinking water use impairment on Sterling Run, Ohio EPA, through a U.S. EPA contractor developed Ohio's first TMDL report specifically for a public water supply. The White Oak Creek watershed TMDL report, which includes Sterling Run, prepared TMDLs for atrazine, fecal coliform, nitrate+nitrite, total suspended solids, total phosphorus and ammonia. In 2009, a Clean Water Act Section 319 grant was awarded that funded atrazine reduction best management practices in the Sterling Run subwatershed. The final TMDL report was approved by U.S. EPA on February 25, 2010.

Ohio EPA is in the process of developing a TMDL report that address atrazine impacts to Swift Run Lake, which is the public water supply source water for the City of Piqua.

Algae (cyanotoxin) Indicator. Since the end of the last report cycle, incidents of harmful algal blooms (HABs) impacting Ohio public drinking water supplies have greatly increased. Algal toxin sample data collection has also increased in response to these incidents. This has included both Ohio EPA data collection and public water system data collection efforts. From 2010 – 2015, more than 3,700 algal toxin samples have been collected and analyzed from Ohio PDWS intakes.

Sufficient data were available to list 19 AUs (15 percent) as impaired. The impairment listing includes the entire Lake Erie Western Basin shoreline, Lake Erie Central Basin shoreline and Lake Erie Island shoreline AUs. In addition, 15 WAUs are now assessed as impaired. While microcystin is the predominant cyanotoxin impacting attainment determinations, saxitoxin has been found responsible for impairment in two WAUs. An additional 19 AUs were also placed on the watch list. With the passage of new HAB rules in Ohio in 2016, data to assess all 123 PDWS AUs will be available for the next IR report cycle.

WAUs that are impaired or on the watch list for cyanotoxins are found distributed across Ohio virtually in every geographic region (Figure H-4).

Cryptosporidium Indicator. Since Ohio EPA has not yet formalized water criteria for *Cryptosporidium*, assessment of this indicator could not be included in this report nor used for Ohio's 2016 303(d) listings. Ohio EPA requested all available *Cryptosporidium* data from U.S. EPA and summarized the results to demonstrate how the data would be evaluated using the PDWS assessment methodology.

Cryptosporidium data are available for 124 public water systems. This dataset included samples collected from 2006 to 2012 in order to fulfill new SDWA regulations that require the water systems to submit 24 to 47 samples over a two-year period. Round 1 of data collection was completed in 2012. Round 2 of sampling began in 2015 with completion scheduled for 2017. The Round 2 data will be assessed for the next report.

The highest average (in oocysts/L) in any 12 consecutive months is compared to SDWA Bin classifications 1 through 4. Any water systems with an average *Cryptosporidium* concentration between 0.075 and less than 1.0 oocysts/L would be placed in Bin 2. Most Ohio public water systems using surface water are already meeting the treatment levels required for this bin. Concentrations equal or greater than 1.0 oocysts/L place the system in Bin 3 or 4 and require additional treatment beyond conventional or source water controls in the watershed, resulting in significant expenditures for the community. Ohio EPA's proposed water quality criteria and watch list condition for *Cryptosporidium* correlate to these trigger concentrations for the Bins.

A review of available data indicates that no water systems have exceeded the 1.0 oocysts/L 12-month average. Ten water systems had average concentrations between 0.075 oocysts/L and 1.0 oocysts/L and met the threshold for the watch list. Watch list water systems are: Akron, Fremont, Berea, Delaware, Westerville, Newark, Greenville, Cambridge, Napoleon and Sebring.

Figure H-2. AUs with nitrate indicator results.

Figure H-3. AUs with pesticide indicator results.

Figure H-4. AUs with algal toxin indicator results.

Table H-2. Waters designated as impaired for (not supporting) the PDWS beneficial use.

Assessment Unit	Cause of Impairment	Summary of Key Water Quality Data
04100005 90 01 Maumee River Mainstem (IN border to Tiffin River)	Nitrate One public water system had at least one excursion above the nitrate WQC and finished nitrate levels above the WQC. Original impairment listed in 2008.	The City of Defiance exceeded the nitrate WQC in finished water during three events (12/24/02-1/28/03; 6/17/03-6/19/03; and 5/15/06-5/16/06). None of the excursions occurred during the reporting period, but the impairment will remain until raw water is collected that supports delisting the assessment unit. A watch list level exceedance occurred on 1/14/13 (8.73 mg/L) and there were seven samples collected by the public water system at their intake that exceeded the WQC (>10 mg/L), indicating more data is needed to delist.
04100007 04 03 Honey Run	Algae One public water system had intake microcystins concentrations above the threshold in August, October and November 2015.	The City of Lima's Williams Reservoir and Bresler Reservoir had a total of seven raw water microcystins sample results greater than the threshold in the Fall of 2015. Included were 11/2/15 results of 25 ug/L (Williams) and 39 ug/L (Bresler).
04100007 03 02 Lower Bad Creek	Nitrate One public water system had two excursions above the Nitrate 10.0 mg/L WQC.	Nitrate Samples collected from source water for Delta Public water system exceeded WQC in 2015. Included were 17.6 mg/L on 6/11/15 and 13.4 mg/L on 7/14/15.
04100009 06 03 Haskins Ditch – Maumee River	Algae One public water system had numerous microcystins concentrations above the threshold.	During 2013-2014, the microcystins threshold was exceeded at the Bowling Green public water system reservoir raw water 19 times. For 2015, the average concentration for microcystins exceeded 7.0 ug/L.
04100009 90 01 Maumee River Mainstem (Tiffin River to Beaver Creek)	Nitrate One public water system had several excursions above the nitrate WQC during the 5-year period. The public water system had finished nitrate levels above the WQC and received SDWA violations.	Finished water nitrate excursions reported for Campbell's Soup on 12/27/12 (11.3 mg/L), 12/31/12 (12.5 mg/L) and 6/18/14 (10.6 mg/L). In June 2015, finished water sample results exceeded 8.0 mg/L at Napoleon and Campbell's Soup.

Assessment Unit	Cause of Impairment	Summary of Key Water Quality Data
04100009 90 02 Maumee River Mainstem (Beaver Creek to Maumee Bay)	Nitrate One public water system had at least one excursion above the nitrate WQC during the 5-year period. Algae One public water system had at least two raw water samples above the threshold for microcystins.	Numerous Maumee River samples from 2012 to 2015 exceeded the Nitrate WQC. In addition, raw water from Bowling Green exceeded the nitrate WQC during three events in 2011 and 2012 Bowling Green's raw water intake on the Maumee River exceeded the microcystins threshold four times in limited sampling conducted in 2014 and 2015.
041000110 02 04 Raccoon Creek 04100011 12 02 Beaver Creek 04100011 12 03 Green Creek	Algae One public water system had numerous microcystins concentrations above the threshold.	For the City of Clyde public water system, Raccoon Creek Reservoir and Beaver Creek Reservoir raw water sample results for microcystins routinely exceeded the threshold in 2014 and 2015. Included was a maximum of 300 ug/L in July 2015 on Beaver Reservoir.
04100011 90 02 Sandusky River Mainstem (Wolf Creek to Sandusky Bay)	Nitrate One public water system had an excursion above the nitrate WQC during the 5-year period in both raw and finished water. This public water system also received SDWA violations.	The City of Fremont exceeded the nitrate WQC in May 2010 (13 mg/L). In addition, Sandusky River samples exceeded the nitrate WQ criteria numerous times from 2010-2015.
04100012 06 03 Norwalk Creek	Algae One public water system had at least two raw water samples above the threshold for microcystins.	Norwalk public water system reservoir sampling had 22.7 ug/L microcystins on Memorial Reservoir in August 2014 and results greater than 5.0 ug/L in June and July 2015.

Assessment Unit	Cause of Impairment	Summary of Key Water Quality Data
04110002 01 01 East Branch Reservoir-East Branch Cuyahoga River 04110002 01 04 Ladue Reservoir- Bridge Creek 04110002 02 03 Lake Rockwell- Cuyahoga River	Algae One public water system had at least two raw water samples in each assessment unit with microcystins concentrations above the threshold.	Source waters for Akron had microcystins levels above the drinking water threshold on at least two occasions in 2010. Maximum raw water microcystins concentrations were 43.0 ug/L in LaDue reservoir, 3.6 ug/L in East Branch reservoir and 3.2 ug/L in Lake Rockwell.
05030201 01 01 Upper Sunfish Creek	Algae One public water system had at least two raw water samples above the threshold for microcystins.	Raw water sampling for Woodsfield public water system from Ruble Lake and Witten Lake exceeded the microcystins threshold in 2015. Included were 1.6 ug/L from Witten Lake on 9/2/15 and 1.4 ug/L from Ruble Lake on 10/13/15.
05040001 01 04 Wolf Creek	Algae One public water system had at least two raw water samples exceeding the saxitoxins threshold.	Raw water sample results from Barberton's Wolf Creek Reservoir exceeded the saxitoxins threshold multiple times in 2015. Included were results of 0.25 ug/L on 9/3/15, 0.81 ug/L on 8/22/15 and 0.23 ug/L on 7/23/15.
05040001 15 03 Upper Little Stillwater Creek	Algae One public water system had at least two raw water samples above the threshold for microcystins.	Cadiz raw water sampling from Tappan Lake routinely exceeded the microcystins threshold in 2015. There were 48 results greater than 1.0 ug/L threshold with an average result of 2.9 ug/L. In addition, seven microcystins threshold exceedances occurred in 2014.
05080001 07 05 Garbry Creek-Great Miami River	Pesticides One public water system had the pesticide atrazine in source water where the annual average exceeded the WQC.	The City of Piqua uses several surface water sources and participates in Syngenta Crop Protection's AMP ¹ . Swift Run Lake (impounded section of Swift Run) is one of the three drinking water sources and the atrazine annual average ² was 3.62 µg/L in 2008. In 2011, atrazine results remained at levels of concern with several lake samples exceeding 12.0 ug/L (4xWQ criteria). This included 38.5 ug/L in June 2011.
05090201 08 02 Headwaters Straight Creek	Algae One public water system had at least two raw water samples exceeding the saxitoxins threshold.	During 2015, raw water sampling on Sycamore Run Reservoir (Waynoka Regional public water system) indicated several exceedances of the threshold for saxitoxins. Included are: 0.29 ug/L (12/7/15), 0.68 ug/L (10/29/15), 0.49 ug/L (8/17/15) and 0.82 ug/L (6/26/15).

Assessment Unit	Cause of Impairment	Summary of Key Water Quality Data
05090201 10 01 Sterling Run	Pesticides One public water system had the pesticide atrazine in source water where the annual average exceeded the WQC.	The Village of Mt. Orab draws surface water from Sterling Run and participates in Syngenta Crop Protection's AMP¹. The 2011 annual average² (6.2 ug/L) exceeded the WQC. In addition, single sample maximum atrazine detections were over four times the WQC in June 2011 (121 ug/L) and April 2012 (18.05 ug/L).
05090202 07 02 Second Creek 05090202 10 05 West Fork East Fork Little Miami River 05090202 13 01 Headwaters Stonelick Creek	Pesticides One public water system had the pesticide atrazine in source water where the annual average exceeded the WQC.	The Village of Blanchester draws surface water from Whitacre Run, Stonelick Creek and the West Fork of the East Fork Little Miami River and participates in Syngenta Crop Protection's AMP¹. The raw and finished water sampling locations for this monitoring program do not differentiate between the three separate source waters. In 2005, the annual average of the AMP samples was 4.63 µg/L and exceeded the WQC for atrazine in finished water. Ohio EPA conducted two sampling runs in 2008 at the three separate sources and measured elevated atrazine levels ranging between 23 µg/L and 70 µg/L. Considering the 2008 atrazine levels, Ohio EPA conservatively applied the impairment listing to all three AUs. In 2012, atrazine concentrations were greater than four times the WQC in samples collected at Stonelick Creek (102.0 ug/L) and the West Fork of the East Fork Little Miami River (89.5 ug/L) and resulting annual averages for atrazine exceeded the WQC in the source water. Finished water result of 21.7 ug/L in May 2014. The impairment listings will remain until adequate source water sampling is conducted to confirm the water source is no longer impaired.
05090202 12 03 Lucy Run-East Fork Little Miami River	Algae One public water system had at least 2 raw water samples with microcystins concentrations above the threshold.	Multiple raw water samples collected from Clermont County public water system source water locations on Harsha Lake (East Fork Lake State Park) exceeded the microcystins threshold. Maximum concentration observed was 190 ug/L in June 2014. Saxitoxins also detected in source water but below the threshold.
05120101 02 04 Grand Lake-St Marys	Algae One public water system had at least 2 raw water samples with microcystins concentrations above the threshold.	The Grand Lake Saint Marys public water system intake for the City of Celina continues to be heavily impacted by microcystins. For 2015, the mean microcystins concentration was 60 ug/L with a maximum observed value of 185 ug/L on 9/21/15. 50 sample results were greater than 1.0 ug/L. Threshold exceedances have occurred every year since the lake was first sampled in 2009.

Assessment Unit	Cause of Impairment	Summary of Key Water Quality Data
24001 001 Lake Erie Western Basin Shoreline (including Maumee Bay and Sandusky Bay)	Algae Six public water systems had at least two raw water samples with microcystins concentrations above the threshold.	Oregon, Toledo, Carroll Township and Ottawa County have all had raw water samples that exceeded the microcystins threshold in 2010, 2011, 2013, 2014 and 2015. Marblehead had raw water samples that exceed the microcystins threshold in 2010 and 2015. Sandusky had raw water samples that exceeded the microcystins threshold in 2014 and 2015.
24001002 Lake Erie Central Basin Shoreline	Algae One public water system had at least two raw water samples above the threshold for microcystins.	Huron had raw water microcystins above the threshold on 9/6/13 (4.6 ug/L) and again on 8/17/15 (2.1 ug/L). In addition, Lake County West, Mentor, Painesville and Fairport Harbor all had raw water microcystins threshold exceedances in 2015.
24001003 Lake Erie Islands Shoreline	Algae Four public water systems had at least two raw water samples above the threshold for microcystins.	Raw water microcystins sample results exceeded microcystins thresholds as recently as 2015. Put-In-Bay had sample results above the threshold in 2010 and from 2013-2015. Kelleys Island had results above the threshold from 2013-2015. Camp Patmos had results above the threshold in 2010 and from 2013-2015. Lake Erie Utilities had results above the threshold in 2014 and 2015.

¹ The January 2003 Atrazine Interim Reregistration Eligibility Decision and subsequent Memorandum of Agreement between U.S. EPA and the atrazine registrants, including Syngenta Crop Protection, Inc., initiated an atrazine monitoring program at select community water systems.

H4. Supplemental Information

Table H-3 provides a summary of PDWS assessment results for the nitrate, pesticide and algae indicators and is organized by assessment unit. A description of the PDWS use zone is also included.

² Annual average calculated as average of the quarterly means for calendar year.

Notes: "Use Support" reports on the PDWS beneficial use status for each assessment unit and is described as follows:

[&]quot;Unknown" = insufficient data to complete the assessment for the PDWS zones within the assessment unit "No" = Innairment of at least one DDWS and within the assessment unit

[&]quot;No" = Impairment of at least one PDWS zone within the assessment unit

[&]quot;Yes" = Full support of the PDWS use within the assessment unit

Following the approval of the 2014 IR, Ohio EPA discovered that some PDWS waters were incorrectly categorized on the 2014 303(d) list (as found in Section L4 of that report), possibly in the original sorting of the PDWS WAUs. The LRAUs and LEAUs were correctly reported. The following table shows the WAUs that were incorrectly identified as "impaired" in Section L4 - 303(d) List of Prioritized Impaired Waters – of the 2014 IR and what the correct category for those waters should have been.

Assessment Unit ID	Assessment Unit Name	Reported Category ²	Correct Category
04100007 03 05	Lost Creek	5	3i
05090202 10 06	Glady Creek-East Fork Little Miami River	5	0
05090202 11 02	Fivemile Creek-East Fork Little Miami River	5	0
05090202 09 02	O'Bannon Creek	5	0
04110001 07 02	Mouth Beaver Creek	5	0
04110002 01 02	West Branch Cuyahoga River	5	0
04110002 02 01	Potter Creek-Breakneck Creek	5	0
05120101 01 01	Headwaters Wabash River	5	0
05080001 06 03	Turtle Creek	5	0
05090202 06 02	Headwaters Todd Fork	5	0
05090201 08 03	Evans Run-Straight Creek	4A	0

Below is the complete list of all AUs that should have been categorized as "impaired" in Section L4 of the 2014 IR and how they were actually reported. These waters were correctly listed as "impaired" in Table H-2 of the 2014 IR.

Assessment Unit ID	Assessment Unit Name	Reported Category	Correct Category
04100005 90 01	Maumee River Mainstem (IN border to Tiffin River)	5h	5h
04100007 03 06	Lima Reservoir-Ottawa River	0	5
04100009 90 01	Maumee River Mainstem (Tiffin River to Beaver Creek)	5h	5h
04100009 90 02	Maumee River Mainstem (Beaver Creek to Maumee Bay)	5h	5h
04100011 90 02	Sandusky River Mainstem (Wolf Creek to Sandusky Bay)	5	5
04110002 01 01	East Branch Reservoir-East Branch Cuyahoga River	0	5
04110002 01 04	Ladue Reservoir-Bridge Creek	0	5
04110002 02 03	Lake Rockwell-Cuyahoga River	0	5
05080001 07 05	Garbry Creek-Great Miami River	0	5
05090201 10 01	Sterling Run	0	4A
05090202 07 02	Second Creek	0	5
05090202 10 05	West Fork East Fork Little Miami River	0	5
05090202 12 03	Lucy Run-East Fork Little Miami River	0	5
05090202 13 01	Headwaters Stonelick Creek	0	5
05120101 02 04	Grand Lake-St Marys	0	5
24001 001	Lake Erie Western Basin Shoreline (including Maumee Bay and Sandusky Bay)	5	5

² Category descriptions are as follows: 0 = no waters currently utilized for water supply; 1 = use attaining; 3i = use attainment unknown because of insufficient data; 4A = impaired, but a TMDL has been completed; 5 = impaired and a TMDL is needed; 5h = impaired based on historical data and a TMDL is needed.

Considerations for Future Lists

Case: 3:17-cv-01514-JGC Doc #: 1-12 Filed: 07/18/17 239 of 601. PageID #: 1236

As new ideas are introduced and in the general course of progress, it is natural for evaluation and reporting of water quality conditions to evolve. Since the introduction of the Integrated Report format in 2002, methods for evaluating the recreation use, the human health use (via fish contaminants) and public drinking water supply use have been systematically added to the traditional aquatic life use reporting.

This section identifies future reporting possibilities and the status of each. The potential future changes include reporting on more types of waters (wetlands, inland lakes) or reporting on specific pollutants of interest (mercury).

Wetlands

Tables and figures cited in this section are contained in the I1 Wetlands Supplement located at the end of this section.

Ohio EPA's Integrated Report (IR) provides information on the overall condition of Ohio's water resources and also identifies those waters that are not currently meeting water quality goals (Ohio EPA, 2012). It fulfills the requirements under the Clean Water Act (CWA) to report biennially on the current condition of Ohio's regulated waters [305(b) report] and to provide a list of impaired waters [303(d) list]. Despite wetlands being regulated as "waters of the state," until now, Ohio has not developed a strategy for including information on the condition of the state's wetland resources as part of the integrated reporting process. Given the sheer number of National Wetland Inventory (NWI) mapped wetlands in Ohio (n = 134,736), it is obviously not feasible to identify individual wetlands that are considered to be impaired as part of the 303(d) list. The 2012 version of Ohio's IR discussed a plan for incorporating wetland information into future reports, as general 305(b) information by using five primary items:

- 1) identify historic wetland resources using NRCS digital soil survey data;
- 2) identify existing wetland resources using NWI data;
- 3) perform a preliminary off-site wetland condition assessment using a level 1 GIS tool;
- 4) include information on past wetland field assessments within each HUC12 watershed; and
- 5) describe and summarize watershed specific field assessment work.

The 2014 report was our first attempt at implementing this plan. In 2013, Ohio EPA's Wetland Ecology Group (WEG) completed a study focusing on the inclusion of wetland information in the Total Maximum Daily Load (TMDL) process on the Middle Scioto watershed (Gara, Harcarik and Schumacher, 2013). This study provides the framework for incorporating wetland information into this reporting process. The focus of the study was twofold: 1) conduct a probabilistic survey of wetland condition for a current TMDL project in central Ohio using Level 2 [Ohio Rapid Assessment Method for Wetlands (ORAM)] and Level 3 [Vegetation Index of Biotic Integrity (VIBI)] assessment tools and 2) develop a Geographic Information System (GIS)-based Level 1 assessment tool to estimate wetland condition within this survey area. The results of the Level 1 assessment were then compared to those obtained using the more detailed Level 2 and Level 3 field assessments. The Level 1 tool that was developed for the Middle Scioto TMDL study differs slightly from the proposed tool included in the 2012 IR. This updated assessment methodology is based on close statistical relationships between the individual metrics and detailed field assessments previously conducted by the WEG. For this reason, the updated Level 1 tool was used when characterizing wetland condition within each of Ohio's HUC12 watersheds. This information is described in much more detail later on in the Wetlands section of this report.

I1.1 Middle Scioto TMDL

Overview of Middle Scioto TMDL Survey Area

The TMDL survey area chosen for this project was the Middle Scioto River, which is composed of two separate HUC10 watersheds: Indian Run-Scioto River [0506000112] and Scioto Big Run-Scioto River [0506000123]. These watersheds are located in central Ohio, running from southern Delaware and Union counties, along the west side of the Columbus metropolitan area and extending south to Circleville in Pickaway County (Figure 1). A vast majority of the TMDL area is heavily modified from development activities. The Middle Scioto is located entirely within the Eastern Corn Belt Plains ecoregion (Omernik, 1987) and has an area of approximately 307 square miles. It is predominantly composed of urban (48 percent) and agricultural land uses (43 percent) based on the 2006 National Land Cover Dataset (NLCD) (Fry et al., 2011). Only 8 percent of the area is composed of land uses not predominantly influenced by human activity (forest, wetland, open water, etc.) (Figure 2).

Wetland Field Assessment Methods and Results

Wetland Sample Selection

Wetlands to be included in Middle Scioto TMDL study were selected from the database of NWI (U.S. Fish and Wildlife Service, 2006-2007) wetland polygons contained within the two HUC10 watersheds which define the study area: Indian Run-Scioto River [0506000112] and Scioto Big Run-Scioto River [0506000123]. Mapped wetland polygons less than 0.1 acre in size were precluded from the initial evaluation. This reduced the total number of potential sites from 671 to 617 separate emergent (N=401), forested (N=191) and scrub-shrub (N=25) wetlands (Figure 3). A Generalized Random Tessellation Stratified (GRTS) survey design was run to select a subset of sites for inclusion in the study (Stevens and Olsen, 2004). This procedure selects a proportional number of sites in each of the three wetland types, based on the total number of emergent, forested and scrub-shrub wetlands present in the TMDL area. In order to ensure enough wetlands were included to account for sites that would need to be dropped from the study due to mapping errors, wetland conversion, landowner resistance, etc. a total of 50 base sites and 150 oversample sites were selected using the GRTS survey design. The first 50 wetlands on the list that met all necessary criteria and could be successfully accessed by the WEG were the sites included in the final ecological condition analysis for the Middle Scioto TMDL area (Figure 4).

Ecological Condition Assessments

Each of the 50 wetlands was assessed using ORAM version 5.0 (Mack, 2001). ORAM is a rapid assessment that evaluates the ecological condition of a wetland using field survey data collected via visual observation of various environmental factors. Scores range from 0 to 100, with low scores indicating poor ecological condition and high scores assigned to wetlands in excellent condition. Additionally, in order to verify the results obtained using ORAM, a more detailed biological survey was conducted on a subset of 10 sites using the VIBI (Mack, 2007). The VIBI is a Level 3 analysis that requires a detailed knowledge of the plant community and can take several hours of field work to conduct. A total of 10 metrics are scored depending on the type of plant community present and, as with ORAM, the higher the VIBI score generated, the better the ecological condition of the wetland. High ORAM and VIBI scores are typically indicative of wetlands relatively protected from human disturbance. Figure 4 illustrates the location for all ORAM and VIBI survey sites that were conducted within the Middle Scioto TMDL study area. Initial field work was done during the 2010 growing season (17 ORAMs, 10 VIBIs), with the

remainder completed in the summer of 2012 (33 ORAMs).

Additionally, a new, simplified version of the VIBI has been developed by the WEG. This procedure is referred to as the VIBI – floristic quality (VIBI-FQ) and a separate VIBI-FQ score was calculated using field data collected for the traditional VIBI as part of this study. The VIBI-FQ is considered a Level 3 assessment, as it requires a complete analysis of the species composition of the plant community. However, only two metrics are calculated, making the overall analysis and interpretation of the VIBI-FQ more straightforward than the traditional VIBI. Preliminary comparisons between the VIBI and VIBI-FQ show a strong statistical correlation between the two approaches (Gara, 2013).

Results of all wetland field assessments that were conducted in the Middle Scioto TMDL area during the 2010 and 2012 growing seasons are shown in Table 1. Comparing results of the detailed assessments (VIBI and VIBI-FQ) with ORAM scores on the same wetlands yielded very similar results. Both the VIBI (Figure 6; p=0.016, $R^2=53.7$ percent) and the VIBI-FQ (Figure 7; p=0.001, $R^2=76.6$ percent) were strongly correlated to the rapid assessment results captured during the ORAM analysis. Consistency in the answer provided by the rapid Level 2 and detailed Level 3 assessments for these 10 sites validates the accuracy of the probabilistic survey of 50 wetlands using only ORAM.

For all 50 Middle Scioto TMDL area wetlands, the mean ORAM score was 40.6, placing the "average" wetland in the study area in fair condition. The breakdown of the 50 wetlands is as follows: 13 (26 percent) were rated as being in poor condition; 19 (38 percent) were rated as fair condition; 11 (22 percent) were good condition; and 7 (14 percent) were considered to be excellent condition. When compared to the WEG reference dataset of natural wetlands, the Middle Scioto TMDL wetlands appear to be skewed slightly to a lower ecological condition than what would be expected for a random selection of wetlands in Ohio (Figure 5). A Tukey's test comparing the mean ORAM scores for a set of 298 natural wetlands compared with the VIBI antidegradation category shows the strong relationship between ORAM and VIBI that is consistently obtained in various studies of wetlands in Ohio (e.g., Fennessy et al., 2007; Mack and Micacchion, 2007; Micacchion and Gara, 2008). When adding in the Middle Scioto TMDL study wetlands into the analysis, there is no statistically significant difference between the mean ORAM scores for natural wetlands falling in the category 1 range and the mean ORAM score for wetlands assessed as part of this study. Conversely, the Middle Scioto TMDL mean ORAM score was different from natural wetlands scoring as category 2 or category 3 when using VIBI and this difference was statistically significant based on the Tukey test.

Level 1 Assessment

A Level 1 desktop assessment tool was developed to predict ecological condition of mapped NWI wetlands, through the evaluation of a variety of landscape-level GIS data layers. All work related to the development of this Level 1 tool was conducted using ArcGIS 10.0 (Environmental Systems Research Institute, 2011). A total of 23 separate parameters were evaluated for inclusion as individual metrics in the Level 1 assessment tool. Each was compared to two separate buffer areas surrounding vegetation survey area boundaries for all natural wetlands in Ohio EPA's reference wetland database which had been previously assessed by the WEG using the VIBI. A standard VIBI plot measures 20 meters by 50 meters in size and generally represents an area smaller than the overall footprint of the wetland being monitored (in the rare instances that a wetland is too small to accommodate a standard VIBI plot, the plot configuration can be modified slightly when conducting a VIBI).

A total of 298 wetlands have had a digital representation of the precise boundary of the VIBI survey area

generated as part of the study. The two buffers zones are: 1) from the edge of the vegetation plot boundary to a distance of 100 meters ("inner zone") and 2) from the edge of the inner buffer zone to 350 meters ("outer zone").

Selection of Level 1 Metrics

A total of 23 landscape-level parameters were selected and calculated for two separate buffer zones (0 to 100 meters; 100 meters to 350 meters) surrounding the vegetation plot boundaries for 298 natural wetlands that had been previously assessed by the WEG using VIBI. Each of the 23 parameters was then individually compared to three separate field assessments conducted for the natural wetlands (ORAM, VIBI and VIBI-FQ) using a simple linear regression in Minitab. Most of the parameters tested for the two buffer areas showed at least a slight statistical correlation to one or more of the assessments.

A total of ten parameters were selected for inclusion in the Level 1 tool, with each showing a strong correlation to most, if not all, of the three field assessments and for both the inner and outer buffer zones. Results of each of these comparisons for the selected parameters are summarized on Table 2. Additionally, an attempt was made to choose an equal number of environmental factors illustrating both "historic" and "current" conditions surrounding each wetland. Since most available statewide GIS data layers have been developed in the last few decades, "historic" is a relative term meant to convey information related to the previous levels of disturbance present for as far back in time as the data is available. The reasoning was to try and choose geographic data that may provide clues related to the long-term stability of a wetland and its surrounding habitat, which is expected to be associated with resources in better ecological condition. For data layers that have been generated more than two times, such as the NLCD, which is available for 1992, 2001 and 2006, typically the oldest and most recent versions were included as metrics while the intermediate date was removed from consideration. The parameters selected which represent "historic" include the following.

- 1) Landscape Development Intensity (LDI) Index for the 1992 National Land Cover Dataset (NLCD) GIS layer. LDI is a procedure for calculating a human disturbance gradient score for an area. The NLCD is a land use layer created using Landsat satellite data, in which each 30-meter x 30-meter pixel is assigned to one of several discreet land Anderson Level 2 land use categories (Vogelman, et al., 2001). Land use categories contained within the NLCD are assigned an LDI index score, depending on the amount of energy required to maintain the level of disturbance associated with that particular land use (Brown and Vivas, 2005). LDI scores can range from 1.00 to 9.42, with the lowest scores associated with natural habitats and higher scores indicating increasing levels of disturbance.
- 2) "Historic Forest" Canopy Percent. All green-colored areas were extracted from the USGS 7.5 minute topographic maps ("Digital Raster Graphics," or DRGs) as a separate GIS layer, referred to as "historic forest." The source maps used to create the DRGs have a publication date range of 1942 to 1995 for Ohio, with a vast majority (91percent) having been produced in the 1950's and 1960's. This was the earliest source of forest cover information available as a statewide data layer that could be identified.
- 3) "Natural" Land Uses minus "Human Disturbance" Land Uses for 1992 NLCD data. Each individual land use category was evaluated and assigned to either human disturbance dominated, natural, or unknown. Classes in which it was not possible to ascertain an obvious trend (e.g., water, grassland) as to whether these land uses had occurred naturally or due to some level of human disturbance were placed in the "unknown" category and not included in the analysis. For the remaining land uses, the cells of each type were summed together and human-dominated land

- uses were subtracted from natural land uses for each of the two buffer zones.
- 4) 1990 population density estimate within inner and outer buffer zones (U.S. Census Bureau, 1990).
- 5) Percent "Rare" Habitat Types. This is a GIS layer that combines rare plant density data from the ODNR Natural Heritage database (Division of Natural Areas and Preserves, 2008) and muck or sandy soils from the NRCS SSURGO soils data (Soil Survey Staff, NRCS, accessed 2009). Summing information from both of these information sources is intended to identify sensitive habitats which have recorded rare species present and/or have a substrate typical of certain rare wetland ecosystems (bogs, fens, Oak Openings sand prairies).

Parameters representing current, or at least the most recent information, include the following.

- 1) Landscape Development Intensity (LDI) Index for the 2006 National Land Cover Dataset (NLCD) GIS layer (Fry et al., 2011).
- 2) Percent Impervious Surface. This is an ancillary data layer created as part of the 2006 NLCD. Each Landsat 30-meter x 30-meter pixel is assigned a score indicating the estimated percent of the area that is composed of impervious surface (Xian et al., 2011).
- 3) 2001 Percent Forest Canopy. Ancillary data layer created as part of the NLCD. Each Landsat 30-meter x 30-meter pixel is assigned a score indicating the estimated percent of the area is composed of forest canopy (Huang et al., 2003).
- 4) "Natural" Land Uses minus "Human Disturbance" Land Uses for 2006 NLCD data.
- 5) 2010 population density estimate within inner and outer buffer zones (U.S. Census Bureau, 2010).

Although the relationship between any one of these parameters and the field assessments showed a considerable amount of scatter, or "noise," strong statistical correlations were evident with each. These correlations exist for each assessment (ORAM, VIBI and VIBI-FQ) and also for both the inner and outer buffer zones.

A metric score of 0, 3, 7 or 10 was assigned to each parameter, based on the quartile distribution of each for the 298 natural wetlands (Table 3). A Level 1 score was then calculated for both the inner and outer buffer zones by summing the 10 individual metric scores for each. To calculate a final score for each wetland, it was assumed that the zone closest to the wetland assessment area has the greatest influence on the ecological condition of that location. Therefore, to calculate a final score for each wetland assessment area, which incorporated Level 1 information for both buffer zones, twice as much weight was given to the 0 to 100-meter buffer Level 1 score. The final calculation is as follows:

Total Wetland Level 1 Score = (Inner Buffer Level 1 Score*0.67) + (Outer Buffer Level 1 Score*0.33)

Comparison of Level 1 score to field assessment data

A Level 1 score was then calculated for each of the 298 natural wetlands in the database and this score was compared to the field assessment scores for VIBI, VIBI-FQ and ORAM. A positive statistical correlation was clearly evident for each, with ORAM showing the strongest relationship to the Level 1 scores (VIBI: p=0.000, $R^2=31.1$; VIBI-FQ: p=0.000, $R^2=33.2$; ORAM: p=0.000, $R^2=37.8$).

The strong statistical relationship between previously-collected field assessment data and Level 1 information can also be illustrated with boxplots, in which the Level 1 scores for all 298 natural wetlands

is divided into quartiles and compared to VIBI, VIBI-FQ and ORAM scores (Figures 6, 7 and 8, respectively). The mean VIBI score for each Level 1 quartile is different for the lowest three quartiles, based on a Tukey's comparison. There is no statistical difference between the mean VIBI scores for the third and fourth Level 1 quartile, however. This suggests that there may be a threshold level of human disturbance that may need to be crossed before a degradation in wetland ecological condition can be quantified. Once this threshold is reached, VIBI scores decline proportionally to increasing disturbance levels (Figure 6). A similar pattern exists for the VIBI-FQ data, except the mean VIBI-FQ scores are statistically different based on Tukey's comparison for all four Level 1 quartiles (Figure 7). ORAM data also demonstrates this pattern. As with VIBI data, mean ORAM scores are statistically different for each of the first three quartiles, but no difference exists between quartiles three and four (Figure 8).

Middle Scioto HUC12 analysis

The Middle Scioto TMDL area is composed of 11 individual HUC12 watersheds. The breakdown of areaweighted Level 1 scores for these watersheds is as follows: six scored as "limited quality wetland habitat" (category 1, or "poor" condition), four fell in the "restorable wetland habitat" (modified category 2, or "fair" condition) range and one scored as "wetland habitat" (category 2, or "good" condition). None of these 11 HUC12s scored in the "superior wetland habitat" (category 3, or "excellent" condition) range, based on the Level 1 assessment. The same 11 watersheds were summarized using field assessment data for the HUC12 watersheds in which a mean condition score was generated for each watershed having more than one ORAM conducted as part of this study. This eliminated two of the HUC12s, as only a single ORAM score had been completed in each and this simply did not provide enough information to warrant assigning a watershed-level condition score. Of the remaining nine HUC12 watersheds, three had a mean ORAM score placing them in the "limited quality wetland habitat" (category 1, or "poor" condition), four fell in the "restorable wetland habitat" (modified category 2, or "fair" condition) range and two scored as "wetland habitat" (category 2, or "good" condition). As with the Level 1 characterization, none of the HUC12s scored in the "superior wetland habitat" (category 3, or "excellent" condition) range. Comparing these results side by side, along with the breakdown of ORAM scores for the probabilistic assessment of Middle Scioto wetlands, shows a similar pattern, with a majority of the HUCs for both the Level 1 and Level 2 characterizations skewed toward lower ecological condition (Figure 9). The ORAM field assessments had a few sites (7 out of 50, 14 percent) scoring in the highest condition category ("Superior Wetland Habitat" [Category 3]), whereas the Level 1 and Level 2 watershed characterization had none. As all of these Middle Scioto assessments resulted in similar results, it is apparent that landscape-level watershed characterizations may be useful for studies of large geographic areas over time. However, it is also important to note that these coarse, GIS-based assessments do not replace the necessity of field-level assessments when needing to accurately determine the ecological condition of a particular wetland.

11.2 Status of Ohio's Wetland Resources

Ohio's Historic and Current Wetland Resources

Dahl's 1990 report "Wetland Losses in the United States: 1780's to 1980's" identifies Ohio and California as the two states with the highest percent loss of original wetland habitat (90 percent and 91 percent, respectively) (Dahl, 1990). Current high resolution GIS data now exists that allows us to verify the accuracy of the previous estimate for Ohio. Using NRCS Soil Survey Geographic database (SSURGO) data (NRCS, various dates), all areas of the state consisting of mapped hydric soil can be identified. It is inferred that these areas of predominantly hydric soils developed under standing water conditions and,

therefore, are an accurate estimate of historic wetland extent in the state. Figure 10 shows all areas of SSURGO mapped hydric soils in Ohio. Multiplying the percent hydric component of each mapped soil polygon by its area and summing these values statewide, produces an overall estimate of original wetland area for Ohio of 5,344,742 acres, which is remarkably similar to the 5,000,000-acre estimate from Dahl's 1990 publication. Virtually all wetland habitat occurred within the glaciated area of Ohio. Additionally, a majority of the original wetland acreage was located in an area of northwest Ohio referred to as the "Great Black Swamp." This enormous wetland complex represented approximately 60 percent of Ohio's pre-settlement wetlands (~3,000,000 acres) and has been almost completely converted into productive agricultural land. This conversion occurred within a fairly brief period round the time of the Civil War and was accomplished through an elaborately engineered series of surface ditches.

In 2006, Ohio initiated a project to capture high resolution aerial photography for each county in the state. One of the ancillary projects of this Ohio Statewide Imagery Program (OSIP) was the development of an updated layer of NWI wetlands based on photo interpretation of these detailed remotely-sensed datasets (OSIP, 2006-2007). The updated NWI was completed and made available to the public in 2010 (U.S. Fish and Wildlife, 2010). This data layer was the primary resource used to estimate current wetland extent in Ohio. Many of the polygons included in the NWI dataset are open water farm ponds, which would not meet the necessary criteria to be considered a wetland, based on the Corps' delineation procedures. Therefore, for this analysis, only polygons mapped as aquatic bed, emergent, scrub-shrub or forested wetlands were included. Figure 11 is a map of Ohio illustrating the remaining wetland resources based on the mapped NWI wetlands. A total of 134,736 NWI polygons are included in this GIS layer. Summing the entire area yields an estimate of 507,057 acres of existing wetland habitat. This represents a loss of 90.5 percent of Ohio's original wetlands, which is very similar to the estimate included in Dahl's publication. Given the errors inherent in any GIS layer, these figures should be considered to be rough estimates, but are consistent with previous statewide estimates of historic wetland losses in Ohio.

This analysis also illustrated a stark geographic disparity in the distribution of the remaining wetland resources in Ohio. Approximately 29 percent of the remaining mapped NWI area is located in a small, four county area of northeast Ohio (Ashtabula, Geauga, Portage and Trumbull). Additionally, only 1,323 of the NWI wetlands (~1 percent of total NWI polygons) are 50 acres or larger and 39.8 percent of these large wetlands are relegated to this same four county area. For mapped NWI wetlands considered to be very large (500 acres+), this unequal distribution was even more evident, as approximately 70 percent of these very large wetlands occur in the same small area of northeast Ohio. Given the precarious state of wetlands overall in the state, it is our recommendation that private and public funding programs focused on the preservation of water resources should place much greater emphasis on protecting and expanding these remaining large wetlands located in and around this four county area of Ohio.

Statewide analysis of Wetland Condition

In 2015, Ohio EPA completed a National Wetland Condition Assessment "Intensification" study, which was funded by a U.S. EPA wetland program development grant. This study consisted of detailed field assessments of 50 randomly-selected wetlands located throughout the state (Gara and Schumacher, 2015). Both Ohio and U.S. EPA assessment methodologies were used to characterize the condition of these wetlands.

Table 4 displays data from ORAM, VIBI and VIBI-FQ, which have established anti-degradation category scoring breakpoints, compiled by approximate ecological condition ranges ("poor," "fair," "good" and

"excellent"). Somewhat surprisingly, more than half of all wetlands had ORAM scores that fell in the "good" or "excellent" ranges. Similarly, for both VIBI and VIBI-FQ assessments, exactly 50 percent of the wetlands surveyed with both of these protocols fell within the upper range of ecological condition. The ORAM, VIBI and VIBI-FQ intensification study results were also compared to the same assessments conducted on a dataset of 263 natural reference wetlands, surveyed from 1999 to 2010 by Ohio EPA and broken down by ORAM anti-degradation category. In each of these box and whiskers plots [VIBI (Figure 12), VIBI-FQ (Figure 130 and ORAM (Figure 14)], the mean value generated from the 50 intensification sites corresponded most closely with the mean value for VIBI, VIBI-FQ and ORAM for high category 2 wetlands grouping ("good" quality) from the reference database. For each of these assessments, mean values were compared using a Tukey's HSD (honest significant difference) test. The mean VIBI, VIBI-FQ and ORAM values for the 50 intensification wetlands were significantly different from the "poor," "fair" and "excellent" condition reference wetland groups in all cases. Only the group of "good" condition wetlands showed no significant difference form the intensification study wetlands for the three assessments. Based on the consistency of these results among these different comparisons, performed on a random selection of sites across the state, it appears that Ohio's remaining wetlands are in "good" overall ecological condition. This is higher than expected, given the amount of wetland loss experienced historically. However, it is important to emphasize that the 90 percent of Ohio's wetlands that have been lost are no longer providing any wetland functions, making the remaining resources that much more important, regardless of relative ecological condition.

HUC 12 Watershed Level 1 Assessment

In order to generate a wetland condition score for each HUC12 watershed in the state of Ohio, a Level 1 assessment was run for each mapped wetland, based on the most current GIS layer of wetland resources available: the NWI layer (U.S. Fish and Wildlife Service, 2006-2007). The NWI has been updated for Ohio using recent high resolution digital orthophotography captured as part of the Ohio Statewide Imagery Program (OSIP, 2006-2007). The complete NWI layer for Ohio contains 313,390 polygons, which includes several types of water bodies that are generally not considered to be wetlands (e.g., rivers, streams, lakes, ponds, etc.). For this analysis, only NWI polygons classified as emergent, scrub-shrub or forested wetlands were included, which reduces the total number of polygons for Ohio that needed to be processed to 134,736. Each of these NWI wetlands was then converted to a center point to ensure that an interior part of each wetland, which would be the most likely to be protected from human disturbance, would represent the most central location for the analysis. This approach is expected to be the most conservative (i.e., generate the highest Level 1 score) and, therefore, most protective of each resource. It is not the intention of Ohio EPA to have Level 1 assessments supersede the need to perform Level 2 and Level 3 field assessments when wetland impacts are proposed as part of a 401 WQC or isolated wetlands permit proposal. Rather, the Level 1 score is intended for use as a planning tool, such as when considering multiple corridors for large transportation projects, or when characterizing large watershed areas, as is the case with the IR.

An inner (0 to 100 meters) and outer (100 to 350 meters) buffer was created surrounding the center point for each of the 134,736 NWI wetland polygons in Ohio. Level 1 parameter scores were generated for each of these mapped wetlands and a final Level 1 score calculated using the previously discussed methodology. HUC12 wetland Level 1 assessment scores were then developed for each watershed by first determining the relative area of all NWI wetlands contained within each of these HUC12s. Relative area values were multiplied with the Level 1 scores and summed by HUC12 watershed to calculate an area-weighted Level 1 score for each. A total of five HUC12 watersheds had no mapped NWI wetlands present and these were assigned a Level 1 score of "0."

Preliminary Level 1 scoring ranges were established to approximate the four wetland tiered aquatic life uses previously proposed by Ohio EPA (Mack, 2004). These ranges are based on the quartile distribution of all NWI wetlands in Ohio and are as follows:

- 1. "Limited Quality Wetland Habitat" (Category 1) = Level 1 scores from 0 to 29.
- 2. "Restorable Wetland Habitat" (Modified Category 2) = Level 1 scores from 29 to 42.
- 3. "Wetland Habitat" (Category 2) = Level 1 scores from 42 to 61.
- 4. "Superior Wetland Habitat" (Category 3) = Level 1 scores from 61 to 100.

The WEG will continue to re-evaluate these Level 1 scoring ranges as more field assessment data on natural wetlands is collected.

Figure 15 depicts all 1,538 watersheds in Ohio based on the area-weighted Level 1 scores, color-coded by the proposed wetland tiered aquatic life use ranges described above.

An analysis was done to compare results of the Level 1 HUC12 watershed characterization with field assessment results (ORAM, VIBI and VIBI-FQ) obtained for natural wetlands in Ohio. Only HUC12 watersheds, which had at least two field assessments conducted, were included in this analysis (N=74). The comparison confirms that a significant statistical relationship exists between the Level 1 and Level 2/Level 3 HUC12 watershed characterizations. This relationship is consistent for VIBI (p=0.000, R²=34.8), VIBI-FQ (p=0.000, R²=30.3) and ORAM (p=0.000, R²=32.5).

Summary Table of Wetland Condition for Ohio's HUC12 Watersheds

The Level 1 analysis documented in this study provides a mechanism for estimating wetland condition on a watershed scale, by generating an area-weighted Level 1 score for each HUC12 watershed in the state. This information, along with data on estimates of overall quantities of historic and current wetland habitat, wetland loss and field assessment data, where it exists, has been summarized for all of the 1,538 HUC12 watersheds in the state (Table 5). No additional random wetland watershed surveys have been conducted since the completion of the 2014 IR, so the information presented in this table has not changed. As new information is generated on Ohio's wetland quantity and quality, this table can be modified for future IRs.

I1.3 Next Steps

Ohio EPA proposes that periodic Level 2 and Level 3 field assessments be conducted on a random selection of wetlands within targeted HUC12 watersheds on a rotating basin schedule, similar to what is currently being done with Ohio EPA stream assessments. Issues such as property access and lack of staff resources will dictate the number of watersheds that can be surveyed, but as the number of HUC12s that have had field assessments conducted increases, a better understanding of the relationship between the Level 1 and Level 2/Level 3 characterizations will be illustrated. This understanding will be critical to the continued improvements to our ability to assess the ecological condition of wetlands using remotely-sensed, landscape-level GIS data. Current staffing resource issues have prevented us from expanding the ecological monitoring program to include regular watershed-scale wetland surveys at this time.

Ohio EPA will be establishing a workgroup of wetland experts to develop criteria for identifying wetlands that would qualify as "special waters." These criteria could include setting specific numeric scores for the Level 1, 2 and 3 assessments, as well as rarity of wetland type and functional capacity within the local

watershed context. One product of this workgroup would be a list of important Ohio wetlands to be included in the IR as being of statewide significance and worthy of extra regulatory protection.

Future research will also focus on improved wetland mapping using the ever-increasing wealth of detailed GIS data, to enhance our ability to more accurately identify the type and extent of wetlands in Ohio.

12. Mercury Reduction at Ohio EPA

Mercury is a persistent bioaccumulative toxic metal that is widely used in many products. Once mercury is released into the environment its toxicity, persistence and ability to travel up the food chain are important issues for human health and the environment. Ohio has a statewide health advisory for mercury from fish consumption for sensitive populations: women of childbearing age and children fifteen years old or younger (issued by the Ohio Department of Health).

U.S. EPA is allowing states to identify waters for a special 303(d) list category devoted to mercury issues (5M). While moving in this direction would be preferable as a way to focus on this important pollutant, Ohio EPA has decided that such a move is not possible for this report. At the same time, Ohio EPA is taking action to decrease mercury pollution and these efforts are summarized here.

I2.1 Ohio Law

House Bill 443 was made law on January 4, 2007. The law has the mercury product regulations created initially in House Bill 583 and Senate Bill 323, establishing sales bans for certain mercury products. Public and private schools through high school were not to purchase mercury, mercury compounds or mercury-measuring devices for classroom use as of April 6, 2007. Mercury thermometers and mercury-containing novelty items were not to be sold in Ohio as of October 6, 2007. The sale of novelty items that have mercury cell button batteries were banned as of 2011. Mercury thermostats were not to be sold or installed as of April 6, 2008. There are exemptions to the sales bans.

12.2 Ohio Projects

Ohio EPA works in several areas seeking to reduce mercury emissions and increase awareness:

- identification of air sources of mercury, including identification of water bodies in the State
 impaired by mercury predominantly from atmospheric deposition, potential emissions sources
 contributing to deposition in the State and adoption of appropriate State-level programs to
 address in-state sources;
- identification of other potential multi-media sources of mercury, such as mercury in products and wastes and adoption of appropriate State-level programs (note that mercury-containing products may be a source of mercury to the air and other media during manufacturing, use or disposal);
- quantifying multi-media mercury reductions achieved by scrubber systems installed at Ohio power plants in response to a lawsuit filed by several northeastern states;
- adoption of statewide mercury reduction goals and targets, including percent reduction and dates of achievement, for air and other sources of mercury, as well as reduction targets for specific categories of mercury sources where possible;
- multi-media mercury monitoring, including water quality, air deposition and air emissions monitoring;

- publicly-owned treatment works with mercury variances implement Pollutant Minimization Programs to identify and reduce sources of mercury that discharge to their plants¹;
- investigating mercury in various types of wastewater, including:
 - o primary materials industries, including primary metal production, oil refining and coal facilities;
 - o facilities processing steel scrap (continuous casting and steel foundries);
 - O publicly-owned treatment works, which looks at indirectly discharging industries through the pretreatment program and facility Pollutant Minimization Plan;
 - O coal power plant wastewater from scrubbers, ash ponds and "Low Volume" wastewaters; and
 - O other industries in interactive allocation segments to get an accurate accounting of mercury in the segments.
- working to control discharges from the state's one mercury cell sodium/chlorine plant²;
- public documentation of the State's mercury reduction program in conjunction with the State's IR and public reporting of progress in carrying out the State's programs and reducing in-State mercury sources; and
- coordination across states, where possible, such as multi-State mercury reduction programs. Ohio EPA has representatives in several organizations that work toward this goal.

In addition, several specific projects are underway as described below.

Mercury Collection and Recycling

Mercury collection and recycling occurs at several businesses in Ohio. Names and contact information for these facilities are available on the Ohio EPA mercury recycling vendor website (http://www.epa.ohio.gov/ocapp/Recycle.aspx).

Mercury Switch Removal Program moved to the National Program

In September 2006, Ohio was one of the first states to partner with the National Mercury Vehicle Switch Recycling Program (NMVSRP) to collect automobile mercury switches. Initially Ohio administered the incentive program. While Ohio EPA administered the program, auto recyclers in Ohio collected for recycling 41,310 mercury-containing automobile switches and \$123,900 in incentives were awarded. NMVSRP took over all aspects of Ohio's switch collection program in September, 2008 including incentives. Currently Ohio works to direct auto recyclers to the national program and assist them when they have questions.

¹ The facilities track implementation of mercury reduction measures and monitor influent and effluent mercury levels. They facilities compile reduction information and submit annual progress reports to Ohio EPA.

² The current consent order includes reducing fugitive air emissions that have contributed to storm water discharges of mercury. The plant will be scrubbing cell emissions with water and sending those discharges to the plant's zero discharge process treatment system. The consent order also requires the company to track mercury mass balances through the facility, and recycle where possible. This includes using collected storm water as process water make-up

Ohio Good DEED Program

The Ohio Dental Association (ODA) initiated the Good DEED (Dedicated to Environmental Excellence in Dentistry) program on May 31, 2010. It is a voluntary program that uses a tiered approach to recognize dental offices that minimize the environmental impact of their practices on Ohio's environment. It includes: comprehensive on-line checklists to identify American Dental Association best management practices (BMPs); environmental regulations that apply specifically to dental offices; and BMPs to help a business be more sustainable and preserve and protect natural resources.

Ohio Hospital Project

Ohio EPA works with the Ohio Hospital Association to reduce the generation of hospital waste, including mercury, which hospitals commonly have in thermometers, blood pressure monitors and other equipment. A formal agreement between the two organizations was signed as part of Ohio Pollution Prevention Week, September 20-24, 1999. The Ohio Healthy Hospitals Pollution Prevention Initiative is based on a federal agreement signed by U.S. EPA and the American Hospital Association. The goal of the program is to provide tools to support hospitals' continued efforts to minimize the production of pollutants and reduce the amount of waste generated.

12.3 Interagency Groups

Members of Ohio EPA are involved in several collaborative groups with representatives from various organizations and agencies. Some of these groups include the following:

- Great Lakes Regional Collaboration (GLRC) formed with members from the federal Great Lakes Interagency Task Force, the Council of Great Lakes Governors, the Great Lakes Cities Initiative, Great Lakes tribes and the Great Lakes Congressional Task Force. The group includes members from non-governmental organizations and other interests in the Great Lakes Region. The GLRC created a strategy (released in December 2005) to restore the Great Lakes basin. Most recently the GLRC released a draft document that describes a strategy to phase-down mercury in products within the Great Lakes drainage area, which includes a portion of northern Ohio. In 2014 the GLRC released a draft progress report.
- Binational Toxics Strategy Mercury Workgroup the Binational Toxics Strategy Mercury
 Workgroup is comprised of representatives from state governments, the United States and
 Canadian federal governments and several environmental groups. Its purpose is to set mercury
 reduction goals applicable to the aggregate of releases to the air nationwide and of releases to
 the water within the Great Lakes Basin.
- Ohio River Valley Water Sanitation Commission (ORSANCO) National Pollutant Discharge
 Elimination System (NPDES) Workgroup this on-going workgroup developed a common
 framework for monitoring power plant ash pond and scrubber discharges for low-level mercury.
 These data will be used, along with ORSANCO's mixing zone phase-out, to reduce mercury
 discharges to the Ohio River.
- Quicksilver Caucus the Quicksilver Caucus (QSC) was formed in May 2001 by a coalition of state
 environmental association leaders to collaboratively develop holistic approaches for reducing
 mercury in the environment. QSC members who share mercury-related technical and policy
 information include the Environmental Council of the States (ECOS), the Association of State and
 Territorial Solid Waste Management Officials (ASTSWMO), the National Association of Clean Air

Agencies (NACAA), the Association of State and Interstate Water Pollution Control Administrators (ASIWPCA), the Association of State Drinking Water Administrators (ASDWA) and the National Pollution Prevention Roundtable (NPPR). The QSC's long-term goal is that state, federal and international actions result in net mercury reductions to the environment. The QSC is working collaboratively and in partnership in three priority areas:

- O stewardship approaches for reducing mercury in the environment and managing safe, long-term storage of elemental mercury nationally and internationally
- o multi-media approaches for a mercury-based TMDL taking into account the contributions of the air and waste program as well as using their statutes to craft solutions
- O approaches to decrease the global supply and demand for mercury.

In 2013, the QSC developed a report that explored the problems associated with mercury occurring in select products, processes and technologies not yet thoroughly examined by experts in the field, such as tattoo inks and nanomaterials. Development of the report was supported by a grant from U.S. EPA.

• Ohio Sport Fish Consumption Advisory – the current Ohio Sport Fish Tissue Monitoring Program has monitored contaminants in sport fish since 1993. Three state agencies participate: the ODNR, Ohio EPA and the Ohio Department of Health (ODH). Both ODNR and Ohio EPA collect fish throughout Ohio's jurisdictional waters. Ohio EPA analyzes the fish samples, reviews the data and issues fish consumption risk assessment evaluations. ODH releases fish consumption advisory issuance information to the public and provides fish consumption information to Ohio citizens as part of the Women's, Infant's and Children's (WIC) and the Help Me Grow (HMG) Programs' activities. Information is distributed where fishing licenses are sold, through pamphlets available in four languages and via the Internet. More information on fish advisories can be found online at http://www.epa.ohio.gov/dsw/fishadvisory/index.aspx.

12.4 Ohio Resources

A number of videos, fact sheets and presentations are available on Ohio EPA's website that relate to mercury. These include household mercury fact sheets; an introduction to mercury issues; a guide for dealing with mercury by school administrators; an informational sheet for building awareness of mercury in schools; information about mercury in industry; and suggestions for developing a community mercury reduction program. See http://epa.ohio.gov/ocapp/p2/mercury pbt/mercury.aspx for more information.

13. Inland Lakes and Reservoirs

Ohio EPA initiated a renewed monitoring effort for inland lakes in 2008. This report assesses three of the four beneficial uses that apply to inland lakes: recreation, public drinking water supply and human health (via fish tissue). Ohio EPA is in the process of updating the water quality standards rules for lakes. Once these rule updates are complete, Ohio EPA expects to include an assessment of the aquatic life use for lakes as a factor in listing watershed or large river assessment units in future CWA Section 303(d) lists. This section outlines the current status of the monitoring effort for inland lakes; summarizes needed administrative rule changes; and previews a potential methodology for assessing the lake habitat aquatic life use in future 303(d) lists. The section was first introduced in 2010 and has not changed appreciably since 2010 because the administrative rule changes have not yet occurred. Ohio EPA intends to continue

monitoring inland lakes and reporting results in future cycles.

13.1 Background of Ohio's Inland Lake Water Quality Monitoring Program

Ohio EPA's work to assess lakes began in 1989 with a CWA Section 314 Lake Water Quality Assessment grant that supported the evaluation of 52 lakes. Various additional grants enabled the evaluation of 89 more lakes through 1995. An analysis and determination of beneficial use status for 447 public lakes (greater than five acres in surface area) was presented in Volume 3 of the 1996 Ohio Water Resource Inventory [305(b) report]. As part of that report, Ohio EPA developed and applied the Lake Condition Index (LCI) to characterize overall lake health and to assess beneficial use status.

After dedicated U.S. EPA funding for lakes monitoring ended, Ohio EPA monitored only 53 lakes over the next 10 years. The Ohio LCI, developed by Ohio EPA between 1990 and 1996 to report on the status of lake condition in Ohio, became obsolete with the passage of Ohio's Credible Data Law [House Bill 43 (amended), effective 10/21/2003]. This law requires that all decisions on impairment for surface waters (streams, lakes wetlands) use only level 3 credible data. Ohio's LCI assessment process included a combination of level 2 and level 3 credible data to make impairment decisions.

Ohio EPA began researching ways to re-establish a lakes monitoring program in 2005. During the 2007 field season, Ohio EPA participated in the U.S. EPA-sponsored National Lakes Survey. Ohio was assigned 19 lakes that were selected through a probability-based random selection process. The effort served as a precursor for renewed lake sampling program in Ohio.

13.2 Status of Inland Lakes Program

Ohio EPA currently has resources to monitor up to 16 lakes per year using the strategy described in Section 13.2.1 below. Priority is being placed on lakes used for public drinking water or used heavily for recreation and suspected of being impaired for either of those uses. Secondary priorities still on the horizon because of limited resources include developing a more robust sampling program, expanding to a wider variety of lakes, exploring the use of remote sensing in the screening of water quality in lakes and attempting to track water quality changes in lakes that might be attributed to Section 319 funding and other watershed water quality improvement efforts. The objectives for monitoring inland lakes are to:

- Track status and trends of lake quality
- Determine attainment status of beneficial uses
- Identify causes and sources of impaired uses
- Recommend actions for improving water quality in impaired lakes

In this report, Ohio EPA discusses lake use impairment for recreation, public drinking water and human health (fish tissue) and previews a methodology for including inland lakes in the aquatic life use listing. The aquatic life use listing is dependent on the rule changes to Ohio's water quality standards, which include adoption of nutrient criteria. Once the criteria are adopted into Ohio's water quality standards rules, Ohio EPA expects to be able to definitively report on the status of the aquatic life use of lakes sampled through 2014.

13.2.1 Lake Sampling – Lake Habitat Aquatic Life Use Assessment

Ohio EPA has implemented a sampling strategy that focuses on evaluating the water quality conditions present in the epilimnion of lakes. The sampling target consists of an even distribution of a total of ten sampling events divided over a two-year period and collected during the summer months. Key water quality parameters sampled include total phosphorus, total nitrogen, chlorophyll a, Secchi depth, ammonia, dissolved oxygen, pH, total dissolved solids and various metals such as lead, mercury and copper. Details of the sampling protocol are outlined in the Inland Lakes Sampling Procedure Manual, available on Ohio EPA's web page at: http://www.epa.ohio.gov/dsw/inland-lakes/index.aspx.

13.2.2 Water Quality Standards for the Protection of Aquatic Life in Lakes

Presently, lakes in Ohio are designated as exceptional warmwater habitat (EWH) with respect to the aquatic life habitat use designation. Revisions to Ohio's WQS that would change the aquatic life use from EWH to lake habitat (LH) are in progress. A primary reason for this revision is that in Ohio, a set of biological criteria apply to rivers and streams, whereas no biocriteria apply to lakes. The numeric chemical criteria to protect the LH use will remain the same as the criteria to protect the EWH use that currently applies to lakes, with a suite of nutrient criteria added. A set of numeric criteria that apply to all surface waters for the protection of aquatic life, regardless of specific use designation, will also apply to inland lakes and are referred to as "base aquatic life use criteria" in the proposed WQS rules. The base aquatic life use criteria will be the same aquatic life numeric criteria that currently apply to lakes. Examples include various metals such as copper, lead and cadmium as well as organic chemicals such as benzene and phenol. Specific details concerning the revisions to the water quality standards rules can be reviewed on Ohio EPA's web page at the following address:

http://www.epa.ohio.gov/dsw/rules/draftrules.aspx.

The chemical criteria specific to the LH aquatic life use in the proposed water quality standards rules are depicted in Table I-1. In addition to these parameters, the base aquatic life use criteria that apply to lakes and can be reviewed on Ohio EPA's web page at:

http://www.epa.ohio.gov/portals/35/rules/draft 1-42new base%20ALU%20criteria aug08.pdf.

Table I-1. Proposed¹ lake habitat use criteria.

Note: All criteria are outside mixing zone averages unless specified differently.

¹ Proposed in draft water quality standards rules, August 2008.

A pH is to be 6.5-9.0, with no change within that range attributable to human-induced conditions.

B At no time shall the water temperature exceed the average or maximum temperature that would occur if there were no temperature change attributable to human activities.

13.3 Preview of Future Listings

An important distinction between assessment of aquatic life uses of rivers and streams in Ohio versus lakes is that the former relies on biological monitoring and a comparison of those results to the biological criteria as the assessment tool. Ohio does not have biological criteria that apply to lakes. As a result, the assessment methodology for the lake habitat aquatic life use will rely solely on the results of water

 $^{^{2}}$ T = total.

 $^{^3}$ m = meters; mg/L = milligrams per liter (parts per million); μ g/L = micrograms per liter (parts per billion); s.u. = standard units.

⁴ ECBP stands for Eastern Corn Belt Plains; EOLP stands for Erie/Ontario Lake Plain; HELP stands for Huron/Erie Lake Plains; IP stands for Interior Plateau; and WAP stands for Western Allegheny Plateau.

⁵ These criteria apply as lake medians from May through October in the epilimnion of stratified lakes and throughout the water column in unstratified lakes.

⁶ For dissolved oxygen, OMZM means outside mixing zone minimum and OMZA means outside mixing zone minimum twenty-four-hour average. The dissolved oxygen criteria apply in the epilimnion of stratified lakes and throughout the water column in unstratified lakes.

⁷ These criteria apply as minimum values from May through October.

quality sampling and a comparison of the results to the applicable numeric criteria. This is an obvious and important difference to the weight-of-evidence approach traditionally used by Ohio for rivers and streams.

13.3.1 Methodology Preview: Lake Habitat Use Assessment

The following protocol is intended to be used to determine the attainment status of the LH aquatic life use in a future IR. This is dependent upon the completion of the WQS rulemaking currently in progress, which provide the foundational components necessary to complete the actual assessment process. The proposed protocol for assessing the LH aquatic life use designation for the purpose of this preview is outlined as follows:

- Comparison of individual sample concentrations for any base aquatic life use parameter sampled
 to the base aquatic life outside mixing zone average (OMZA) numeric criterion. If more than 10
 percent of the samples within an assessment period (typically two years) exceed the OMZA
 numeric criterion, the LH use is considered to be impaired.
- 2) Comparison of the ammonia concentrations of the lake samples collected to the LH OMZA numeric criterion. The LH use is considered to be impaired if more than 10 percent of the individual samples exceed the OMZA.
- 3) Comparison of the average dissolved oxygen content of the epilimnetic samples of a thermally stratified lake (or samples throughout the water column of an unstratified lake) to the OMZA dissolved oxygen criteria for the LH use designation. If more than 10 percent of the average dissolved oxygen values do not meet the OMZA criterion, the LH use is considered to be impaired.
- 4) Comparison of the median pH value of the epilimnetic samples of a thermally stratified lake (or samples from throughout the water column of an unstratified lake) to the OMZA pH criteria for the LH use designation. If more than 10 percent of the median pH values do not meet the OMZA criterion, the LH use is considered to be impaired.
- 5) Comparison of the median chlorophyll a concentration of the samples collected over the sample period (typically two consecutive summers) to the applicable chlorophyll a criterion for the type of lake and ecoregion in which the lake is located. The LH use is considered to be impaired if the median chlorophyll a concentration exceeds the applicable chlorophyll a criterion.
- 6) Total phosphorus, total nitrogen and Secchi depth parameters are used to flag potential impairment of the LH aquatic life use designation. Exceedance of these nutrient criteria is determined in a manner similar to that described for chlorophyll a. However, exceedances of the criteria for these parameters will trigger listing on the state's "watch list" rather than a determination of use impairment. Lakes listed on the watch list will be factored into the prioritization process for additional monitoring.

13.3.2 Results

Table I3-2 describes the assessment status of the LH aquatic life use designation for thirteen lakes sampled by Ohio EPA in 2013-2014 based on the protocol outlined in the previous section.

Final Draft

Table I-2. Summary of the lake habitat use assessment for lakes sampled in 2013-2014 using the draft assessment methodology described in this section. Note: Values in red represent an exceedance of criteria resulting in a determination of non-support of the lake habitat aquatic life use designation. Values in yellow represent a watch list designation.

Addressing Waters Not Meeting Water Quality Goals

Case: 3:17-cv-01514-JGC Doc #: 1-12 Filed: 07/18/17 324 of 601. PageID #: 1321

The federal Clean Water Act (CWA) requires that states identify waters not meeting water quality goals and then prioritize them for action to restore their beneficial uses¹. The resulting list of prioritized impaired waters is known as the 303(d) list. Ohio's 2016 303(d) list is presented in Section L4 of this report.

Ohio made substantial changes to its listing process in 2010 (see Sections A and J in the 2010 Integrated Report [Ohio EPA, 2010]); Ohio's 2012 Integrated Report and 303(d) list (Ohio EPA, 2012) contained relatively few changes compared to the major adjustments made in 2010. A significant change to the 2014 report included the addition of a new indicator (algae) to the public drinking water supply (PDWS) use. This 2016 report contains changes in how the information is organized and what data sets were used (for instance, 2015 data was included for both recreation and PDWS uses), but no significant changes in the assessment methods were made. This section outlines the listing framework; lays out the prioritizing and delisting processes and results; and reports on the status of Ohio total maximum daily load (TMDL) efforts including schedules for future TMDLs and monitoring in Ohio.

J1. Ohio's 303(d) Listing Framework

The process of listing involves assigning a condition status (a category) for each of four beneficial uses for each assessment unit (AU). Data requirements, descriptions of available data, assessment methodologies and results were discussed and reported by individual beneficial use in Sections E, F, G and H.

In 2010, Ohio modified the five-category listing structure suggested by U.S. EPA to accommodate listing by beneficial use and introduced subcategories to give more information about the status of each water. In 2012, one additional subcategory, "t," was added to aid reporting the status of AUs relative to approved TMDLs² and data availability. In 2014, the "t" subcategory was altered slightly and a new category "d" was added to better reflect circumstances encountered as Ohio EPA revisits watersheds having approved TMDLs. In 2016, a new subcategory in Category 5 (i.e., 5-alternative or 5-alt) was added to report on alternative restoration approaches for CWA 303(d) listed waters. Such waters will still require TMDLs until water quality standards are achieved. Ohio does not have any AUs listed under 5-alt in this report, but anticipates using this subcategory in the future.

Table J-1 summarizes the categories and subcategories used in this report.

Also in 2010, Ohio began listing by beneficial use within each AU and reporting on a smaller AU size. Watershed AUs shifted from an average size of 130 square miles to 27 square miles. Under the old system, an impairment of one beneficial use caused the AU to be category 5 (impaired) regardless of the status of other uses.

¹ Beneficial uses include aquatic life, human health (fish contaminants), recreation (bacteria) and public [drinking] water supply.

² As discussed in Section C-1, the Ohio Supreme Court ruled in *Fairfield Cty. Bd. of Commrs. v. Nally*, 143 Ohio St. 3d 93, 2015-Ohio-991, that Ohio EPA must follow the rulemaking procedures in Ohio Revised Code Chapter 119 before submitting a TMDL to U.S. EPA for approval. Because none of Ohio EPA's TMDLs have been adopted as rules under R.C. Chapter 119, the effect of the Ohio Supreme Court ruling is arguably invalidation of all previously approved TMDLs. Although Ohio EPA is currently evaluating alternatives for addressing both past and future TMDLs, this situation should be kept in mind while reading this section.

Table J-1. Category definitions for the 2016 Integrated Report and 303(d) list.

	Category ³		Subcategory
0	No water currently utilized for water supply		
		d	TMDL complete; new data show the AU is attaining WQS
1	Use attaining	h	Historical data
'	Use attaining	t	TMDL complete at HUC ⁴ 11 scale; AU attaining WQS at HUC 12 scale
		Х	Retained from 2008 IR
2	Not applicable in Ohio system		
		h	Historical data
		i	Insufficient data
3	Use attainment unknown		TMDL complete at HUC 11 scale; there may be
3		t	no or not enough data to assess this AU at the
			HUC 12 scale
		Х	Retained from 2008 IR
		Α	TMDL complete ⁵
		В	Other required control measures will result in
		В	attainment of use
4	Impaired; TMDL not needed	С	Not a pollutant
		h	Historical data
		n	Natural causes and sources
		Х	Retained from 2008 IR
		alt	Alternative restoration approaches ⁶
		М	Mercury
5	Impaired; TMDL needed	d	TMDL complete; new data show the AU is not attaining WQS
		h	Historical data
		Х	Retained from 2008 IR

Figure J-1 illustrates the significance of these changes in the listing procedures. In the example, an AU listed in 2008 as impaired (*i.e.*, category 5) appeared on the 2010 303(d) list as five units with four uses each; thus, reporting one piece of information changed to reporting 20 pieces of information. Whereas the 2008 list indicated only that the unit was impaired, the new listing indicates all of the following information:

- Aquatic life use is impaired (5) in one unit, not impaired (1) in one and unknown (3) in one. A TMDL to address impairments has been completed in one unit (4A) and the impairment in the remaining unit is being addressed in some other way (4B, e.g., a discharge permit).
- Recreation use is impaired (5) in three units, unknown (3) in one and a TMDL to address the impairment in one unit has been completed (4A).

³ Shading indicates categories defined by U.S. EPA; other categories and subcategories are defined by Ohio EPA.

⁴ HUC means "hydrologic unit code."

⁵ While Ohio has completed these TMDLs and they were approved by U.S. EPA, in March 2015 in *Fairfield Cty. Bd. of Commrs. v. Nally,* 143 Ohio St. 3d 93, 2015-Ohio-991, the Ohio Supreme Court determined that "A TMDL established by Ohio EPA pursuant to the Clean Water Act is a rule that is subject to the requirements of R.C. Chapter 119, the Ohio Administrative Procedure Act." See Section C (page C-17) for more details.

⁶ Ohio currently has no waters that are listed under this subcategory.

- Human health results based on fish tissue analysis indicate that four of the five units are impaired (5) and one is unknown (3).
- Public drinking water supplies exist in only two of the five units and one of those is impaired (5). The status of the other is unknown (3).

Table J-2 shows the number of potential listings that could result from the combination of smaller AUs and listing by individual use.

For the aquatic life use, Ohio EPA continues the transition that began in 2010 of translating data evaluated at the 11-digit hydrologic unit size to the smaller 12-digit size. We expect that the few remaining relic categories will be dealt with as those areas are monitored again.

Figure J- 1. Listing by smaller AUs and individual beneficial uses.

Table J-2. Potential listing opportunities in Ohio's listing framework.

				2010 and After		
AU Types	Number of AUs	Status Reports per Unit	Total Number of Possible Listings	Number of AUs	Status Reports per Unit	Total Number of Possible Listings
Watershed	331	1	331	1538	4	6,152
Large river	23	1	23	38	4	152
Lake Erie shore	3	1	3	3	4	12
Totals	357	1	357	1,579	4	6,316

J2. Prioritizing the Impaired Waters: the 303(d) List

As previously stated, the impaired waters are identified and assigned a category by individual beneficial use in Sections E, F, G and H. After waters are identified as impaired and it is determined that a TMDL is required, the waters are prioritized to produce the 303(d) list (see Section L4). Because Ohio uses a highly integrated monitoring and TMDL linkage to ensure efficient use of resources, it makes sense to

continue to set priorities by AU rather than by individual use.

Ohio River and Open Waters of Lake Erie

Other organizations have lead responsibility for two special waters affected by multiple jurisdictions: U.S. EPA for the open waters of Lake Erie and ORSANCO for the mainstem of the Ohio River. Ohio EPA is actively participating in TMDL and similar actions conducted by these organizations, so priority for *Ohio EPA-initiated action* is assigned a low priority for these waters. TMDLs in watersheds that drain to the Ohio River and Lake Erie will reduce the pollutant load delivered to each water.

Inland Waters and Lake Erie Shoreline

A point system is used to assign priority to impaired AUs. A total of 22 points could be assigned to an AU, distributed as shown in Figure J-3. The priority results for specific AUs are reported in Section L and in AU summary information available on the web page.

Figure J-2. Priority points assigned based on use impairment or other factors (extra points).

The AUs are assigned priority points using the guidelines in Table J-3. The points assigned to the public drinking water and human health uses are straightforward. For the recreation and aquatic life uses, points are assigned based on a computed index score (see Sections F2 and G2). The lowest quartile (scores between 0 and 25) get the fewest points because a TMDL may not be the most effective way to address the impairments. Scores in this range indicate severe basin-wide problems, comprehensive degradation that may require significant time and resources and broad-scale fixes, including, possibly, fundamental changes in land use practices. Education about the effects various practices have on water quality and encouraging stewardship may be more effective in these areas than a traditional TMDL approach. Scores in the highest quartile (between 75.1 and 100) generally indicate a localized water quality issue. Addressing the impairment may not require a complete watershed effort; rather, a targeted fix for a particular problem may be most effective. Thus, these receive the next lowest number

of priority points. The most points are awarded for scores in the middle quartiles (between 25.1 and 50 and between 50.1 and 75), indicating problems of such scale that purposeful action should produce a measurable response within a 10-year period. These waters are the best candidates for a traditional TMDL.

Two additional points may be awarded to AUs that are impaired for the recreation use and contain Class A waters. Class A waters are those most suitable for recreation, such as popular paddling streams and lakes with public access points developed, maintained and publicized by governmental entities.

Table J-3. Priority points for impaired AUs.

		Number	of AUs			
Points	Condition	WAUs	LRAUs			
Human He	alth Use impairment (fish tissue contaminants) (maximum of 3 points)					
2	Listed as impaired for Fish Contaminants (Human Health Use)	427	35			
+1	Additional point in AUs that have greater than 500 ppb PCBs or mercury	1	1			
Recreation	Use impairment (maximum of 6 points)					
1	Listed as impaired, with AU score ⁷ between 0 and 25	77	0			
2	Listed as impaired, with AU score between 75.1 and 100	92	14			
3	Listed as impaired, with AU score between 25.1 and 50	248	2			
4	Listed as impaired, with AU score between 50.1 and 75	272	7			
+2	Additional points if AU contains Class A waters	36	23			
Aquatic Lif	e Use impairment (maximum of 4 points)					
1	Listed as impaired, with AU score between 0 and 25	172	0			
2	Listed as impaired, with AU score between 75.1 and 100	29	9			
3	Listed as impaired, with AU score between 25.1 and 50	121	1			
4	Listed as impaired, with AU score between 50.1 and 75	112	2			
Public Drin	Public Drinking Water Use impairment (maximum of 9 points)					
5	Listed as impaired for Public Drinking Water Use for one indicator	20	3			
+2	Additional points in AUs impaired for each additional indicator	0	1			
1	Not listed as impaired, but on watch list; one point for each indicator	40	4			

As outlined in Section C8, the priority schedule for TMDL projects in Table J-15 was developed considering the above information, as well as the following:

- Social Factors (highly used recreational waters, drinking water supply for significant populations, ongoing/sustained involvement of any local groups or government, etc.)
- Value Added (is a TMDL the most efficient way to achieve improved water quality?)
- Is there an approved watershed action plan if so how many implemented projects?
- How much regulatory authority exists over sources?
- Is there an alternative way to improve water quality more quickly than a TMDL? (e.g. immediate implementation of an existing plan or projects, or imposing more stringent permit limits to address a localized problem)

⁷ The AU score referenced throughout this table is reported on the summary sheets in Section L and on the AU summaries on the web.

- Are there other factors in play? Examples include:
 - o Pending enforcement for a discharger (possible 4B option)
 - o U.S. Army Corps of Engineers modeling of reservoir discharge to improve downstream water quality
 - o Local or statewide strategy or requirements in place to address a particular issue/pollutant (*e.g.* new health department rules for home sewage treatment systems if they are sole/primary source of impairment)

Near Term Priorities for Ohio EPA

Ohio is facing increasing problems with cyanobacteria blooms in inland lakes, including development of HABs in source waters. Many public water systems are experiencing increased treatment costs to manage the extra carbon load and cyanotoxins at their intake. The smaller conventional systems will have difficulty treating water for these problems and the expense will be very high to upgrade those plants.

In the 2014 Integrated Report, Ohio listed waters impaired by algal toxins for the first time. In the 2016 report, more waters are listed, especially lakes and reservoirs. To emphasize protection of the Public Drinking Water Supply beneficial use from HABs, Ohio is making inland lakes used for public water supply a focus for the next several years for monitoring and improving water quality through TMDLs or other approaches.

Based on a review of the inland lakes or reservoirs that were listed as impaired or on the Watch List for algae indicators in the 2014 Integrated Report, as well as the more recent data collected for algae at PDWS with intakes in inland lakes or reservoirs that led to the 303(d) listing in this report, the following inland lakes were chosen as Ohio's priorities for the next few years:

Tappan Lake in Harrison county (upper Little Stillwater Creek)
W.H. Harsha Lake in Clermont County (Lucy Run - East Fork Little Miami River)
Clyde/Beaver Creek Reservoir in Seneca County (Beaver Creek, Green Creek)

The impairments (or watch list parameters) cited include nitrate, pesticides and algae indicators. Where there is a TMDL developed it is older and/or does not include the stream reaches that most impact the lake/reservoir. In most cases, there are active local parties interested and/or there is a sizable population served by these sources. Ohio EPA considers nutrients (primarily phosphorus as the TMDL parameter) to be the priority for the inland lake efforts. However, the cause of impairment in more than one area also includes pesticides and/or nitrates, so other pollutants may be added to the TMDL or alternative plan. These waters are listed on the 303(d) Priority list in Section L4 as follows:

AU Number	AU Name	Sq. Mi. in Ohio	Human Health	Recre- ation	Aquatic Life	PDW Supply	Priority Points
05040001 15 03	Upper Little Stillwater Creek	29.72	1	1	3	5	5
05090202 12 03	Lucy Run-East Fork Little Miami River	32.48	1	1	5	5	7
04100011 12 02	Beaver Creek	29.3	3i	4Ah	4A	5	5
04100011 12 03	Green Creek	30.78	1	5	4A	5	9

While they do not have the highest priority points, the AUs with higher priority points that include a PDWS impairment already have a TMDL under development or will be addressed through other means

such as the Great Lakes Water Quality Agreement Annex 4 nutrient reduction efforts discussed in J3.

Tappan Lake

- Stillwater Creek basin primarily forest with mining influences.
- 2,350 acres of water surface.
- Provides drinking water to the Village of Cadiz (pop. ~ 3,350).
- Lake is operated by the U.S. Army Corp of Engineers. It is a multipurpose project for flood reduction, recreation and fish and wildlife enhancement.
- Assessed by Ohio EPA in 2012-2013 and did not meet the draft lake habitat use criteria.
- 2014 Integrated Report listed the lake as impaired for PDWS based on algae indicators (microcystin).

Figure J- 3. Watershed upstream from Tappan Lake and attainment status of sites from 2012 Stillwater River survey.

William H. Harsha Lake

- Located in the East Fork of the Little Miami River watershed largely agriculture and forest with some urban influence.
- 2,160 acres of water surface.
- Lake is operated by the U.S. Army Corp of Engineers and is a multipurpose project for flood reduction, water supply, recreation and wildlife habitat.
- 2014 Integrated Report listed the lake as impaired for PDWS based on algae indicators (microcystin) and placed it on the watch list for atrazine.

From the Ohio EPA East Fork Little Miami River Technical Support Document, 2014:

- Clermont County operates a community public water system that serves a population of approximately 117,097 people. The water supply sells water to the village of Batavia, village of Williamsburg and New Richmond Robin-Grays water system. Clermont County operates two ground water plants and one surface water plant. The BMW surface water plant draws water from an intake structure on Harsha (East Fork) Lake. The system's treatment capacity is approximately 27.5 million gallons per day, but current average production is 12.5 million gallons per day.
- There are several environmental organizations active in the East Fork Little Miami River watershed. The oldest of these is Little Miami Incorporated (LMI) which has been active for 45 years. Most of LMI's activities have involved the purchase of conservation easements or property purchases in the riparian zone of the river. Clermont County and SWCDs in Clermont, Brown, Highland and Clinton counties formed the East Fork Watershed Collaborative to take advantage of ODNR's Watershed Coordinator Program.
- Several research projects have been initiated in the East Fork watershed and Harsha Lake by U.S. EPA's National Exposure Research Laboratory in Cincinnati and the U. S. Army Corps of Engineers. Among other topics research and monitoring are examining HABs and nutrients, impacts on the Clermont County water intake, carbon sequestration, methane release, nutrient trading, environmental tipping points and fish population genetics. At this time seven different projects are conducting monitoring in Harsha Lake.

Figure J- 4. Watershed upstream from Harsha Lake and the attainment status of sites from the 2012 East Fork Little Miami River survey.

Clyde/Beaver Creek Reservoir (up-ground)

- Sandusky river watershed primarily agricultural land use above reservoir.
- 110 acres of water surface.
- Provides drinking water to the City of Clyde (pop. ~6,320).
- Reservoir was assessed by Ohio EPA in 2009-2010 and did not meet the draft lake habitat use criteria.
- 2014 Integrated Report placed the lake on the watch list for PDWS based on algae indicators (microcystin) and nitrates. The 2016 Integrated Report will list it as impaired for PDWS based on algae indicators.
- The Raccoon Creek reservoir that also serves the City of Clyde is actually filled with water from Beaver Creek. The Raccoon creek reservoir was listed in the 2014 IR as impaired for PDWS based on algae indicators (microcystin).
- A TMDL for the lower Sandusky River was completed by Ohio EPA and approved by U.S. EPA, but did not set specific loads for Beaver Creek since the stream was not listed as impaired.

Figure J- 5. Watershed contributing to Beaver Creek Reservoir and the attainment status of sites sampled in 2009.

J3. Addressing Nutrients in Lake Erie

Ohio is working to address its contribution to the problems in Lake Erie through nutrient TMDLs on tributaries; numerous state initiatives to reduce nutrient loads from Ohio; and active participation on

Annex 4 (Nutrients) and other Great Lakes Water Quality Agreement (GLWQA) efforts. Effective lake management and coordinated implementation are needed to address the Western Basin of Lake Erie algal blooms and the Central Basin hypoxia issues, requiring a multi-state and binational effort. Currently, there are a number of parallel planning and management efforts ongoing at the state, federal and binational level. With regard to the open waters of Lake Erie, respecting and working through the binational governance framework is the appropriate process and Ohio intends to aggressively pursue state measures that complement the process and are neither duplicative nor contradictory.

As water quality has improved through the decades, Ohio EPA has addressed most of the significant point source problems and are now left with primarily nonpoint source related impairments. The current Lake Erie algal blooms and Central Basin hypoxic zone are driven by nutrient loading to the Lake. Recent assessments by the Ohio Phosphorus Task Force (Phases I and II) and Annex 4's Objectives and Targets Task team indicate nonpoint sources are the primary source. A key challenge for nutrient management is to assess and manage both in-stream (near-field) and downstream (far-field) impacts in the receiving waterbody (Lake Erie). To improve water quality in Lake Erie, a separate and independent analysis is needed to determine in-lake goals and seasonal/annual load reductions targets for the tributaries. Ohio is directly involved in developing these goals and reduction targets needed for Lake Erie while moving forward on developing implementation strategies and taking action.

Recognizing there may be confusion about the multiple initiatives and how they fit together to improve Lake Erie, an outline and explanation of linkages is provided below.

Great Lakes Water Quality Agreement

Binationally, the U.S. and Canada are working together under the GLWQA to develop nutrient reduction strategies; come to agreement on phosphorus reduction targets for Lake Erie; and create and implement action plans to meet the targets.

<u>Annex 4</u> of the 2012 GLWQA specifically addresses nutrients in the Great Lakes and contains short-term requirements specific for Lake Erie. U.S. EPA has indicated to Ohio that it agrees that the Annex 4 process is the best way to protect Lake Erie for the four states and one province that share the shoreline.

Work under Annex 4 includes the following:

- Develop binational phosphorus loading targets for Lake Erie (by February 2016)
 - o Released summer 2015 with public consultation and comment period
 - o Final targets/objectives will be included in the binational nutrient management strategy for Lake Erie and will include allocation by country and watershed
- Develop Binational Nutrient Management Strategy (by June 2016), and
- Develop Domestic Action Plans to meet the targets (by April 2018).

Annex 2 of the GLWQA provides the framework for long-term binational management of the Lake. A comprehensive LAMP has been developed for Lake Erie and is the binational platform where whole lake management plans are developed, implemented and tracked. Ohio is a key partner in the binational partnership. For example, Annex 2 calls for creation of a new nearshore framework and the binational partnership will be responsible for implementing the framework and reporting on progress. It is also expected that the nutrient targets from Annex 4 will be incorporated in the next version of the lakewide management plans. Working through the binational partnership is critical for developing a coordinated approach with consistent reporting across the borders.

Great Lakes Commission: Lake Erie Nutrient Targets (LENT) Working Group

The Great Lakes Commission formed the Lake Erie Nutrient Targets (LENT) Working Group as a result of a 2014 resolution that committed the Lake Erie states and the province of Ontario to develop new and refine existing practices, programs and policies to achieve pollutant reduction targets and identify additional remedies to improve water quality in Lake Erie. This is a state/province initiative that is parallel, but separate from the binational GLWQA and Annex 4 efforts. Ohio is a member of the LENT Working Group. The LENT Working Group released a Joint Action Plan for Lake Erie on September 29, 2015, available at http://glc.org/projects/water-quality/lent/.

Lake Erie Collaborative Agreement

The Lake Erie Collaborative Agreement is another state/province led-initiative; it was signed in June 2015 by Ohio, Michigan and Ontario (http://www.cglslgp.org/media/1590/western-basin-of-lake-erie-collaborative-agreement-6-13-15.pdf). The three parties in the agreement are supportive of the binational Annex 4 effort, but recognize that immediate actions can be implemented at the state and provincial levels. In order to get a head start on the Annex 4 process and hasten efforts to improve water quality in Lake Erie, Ohio released a draft Collaborative Implementation Plan in June 2016. The Annex 4 domestic action plans will build on the Collaborative's short-term goals and the implementation plans will become the long-term plans. One of the goals spelled out in the Collaborative Agreement is to reduce nutrient levels going into Lake Erie by 40 percent. The other is to develop a strategic plan to manage dredge material in order to ensure it complies with the state's recent commitment to stop open lake disposal of dredge material into Lake Erie by 2020. The GLWQA does not contain timeframes for implementation and restoration goals, but Ohio is working to meet the Collaborative Agreement phosphorus reduction goals of 20 percent by 2020 and 40 percent by 2025.

TMDLs for Lake Erie Watershed

TMDLs are conducted by the state or federal governments as required under the CWA for waters that have been formally identified as impaired. TMDLs use monitoring and modeling to identify where load reductions and restoration actions are needed. Ohio EPA plans to utilize this tool to target implementation in Ohio's Lake Erie watersheds as it works to meet the Annex 4 phosphorus targets and allocations.

TMDLs are a document that provides guidance on where to focus implementation and recommends BMPs. The TMDL process does <u>not</u> provide additional authority to either Ohio or U.S. EPA to regulate nonpoint sources of pollution; Ohio's regulatory tools are limited to permits and enforcement actions against point sources of pollution.

Ohio has completed TMDLs⁸ for 22 of 32 project areas (watersheds) feeding into Lake Erie and work on the remaining 10 watersheds is underway by either Ohio EPA or a contractor for U.S. EPA. All of these TMDLs employ the State's narrative water quality (WQ) criteria for phosphorus with established targets and methods to address "near field" impacts on rivers and streams. Because Ohio lacks a WQS criterion for total phosphorus concentration in Lake Erie, TMDLs were not developed to address the excessive wet weather loads delivered to Lake Erie. Ohio currently assesses the shoreline zone (shoreline out to 100-meters) of Lake Erie and the aquatic life use is designated as impaired by nutrients, among other

⁸ While Ohio has completed these TMDLs and they were approved by U.S. EPA, in March 2015 in *Fairfield Cty. Bd. of Commrs. v. Nally*, 143 Ohio St. 3d 93, 2015-Ohio-991, the Ohio Supreme Court determined that "A TMDL established by Ohio EPA pursuant to the Clean Water Act is a rule that is subject to the requirements of R.C. Chapter 119, the Ohio Administrative Procedure Act." See Section C (page C-17) for more details.

causes.

There have been questions regarding the Chesapeake Bay approach (federally-led multi-state TMDL) and whether it would be appropriate for Lake Erie's Western Basin. The difference is Lake Erie is bordered by another country and already has a binational governance framework (GLWQA) and implementation tool (Annex 4 Domestic Action Plans) in place. Ohio and the other Lake Erie partners are working with U.S. EPA to understand what worked well under the Chesapeake Bay TMDL and build those tools or actions into the Domestic Action Plans. The Annex 4 process of developing loading targets and Domestic Action Plans are essentially identical to the TMDL process but have the added advantage of being binationally managed according to the GLWQA. Key steps in each process are depicted in Figure J-6.

State TMDL VS Binational Annex 4

Figure J- 6. Key steps in the state TMDL and binational Annex 4 processes.

Ohio-based Efforts

Ohio EPA's NPS Management Plan ("Plan") is the Agency's guiding document that outlines recommended strategies, goals and objectives for controlling nonpoint sources of water quality impairment. The Plan was most recently updated in 2014 and identifies specific management activities to be implemented by Ohio EPA's NPS management program. The recent algal blooms on Lake Erie, the Ohio River and across the inland waters of Ohio are caused by excessive nutrients and exacerbated by changing weather patterns such as warmer temperatures and more intense storm events. The long-term solution is to reduce sources of nutrients while holistically restoring stream health and improving the waterway's ability to assimilate and utilize nutrients. This is also known as the stream's "assimilative capacity." Restoring stream health will not only reduce the amounts of nutrients that reach the receiving water body, but restoration of in-stream and riparian habitat supports a healthy

ecosystem, builds resilience to climate change impacts and improves recreational opportunities. The most current version of Ohio's NPS Management Plan is available at: http://www.epa.ohio.gov/Portals/35/nps/NPS Mgmt Plan.pdf.

Recognizing that Ohio's watersheds provide a significant amount of nutrients to Lake Erie and that its communities are bearing the brunt of algal bloom impacts, Ohio launched a series of initiatives at the state-level back in 2010 and has expanded the scope and scale of implementation; developed a statewide strategy; targeted funding; and undertook legislative action to address the problem. Since 2011, the Ohio has invested more than \$1 billion in the Lake Erie watershed to improve drinking water and wastewater facilities; monitor water quality; plant cover crops; recycle dredge material; install controlled drainage systems on fields; and fix failing septic systems. In addition, Ohio has received more than \$11 million from the Great Lakes Restoration Fund for water quality improvement efforts in the Lake Erie watershed.

The following is a list of several state-led and statewide water quality improvement activities.

- 1. **Statewide Nutrient Reduction Strategy:** Ohio's environmental, agricultural and natural resource agencies worked together to create a statewide strategy to reduce nutrient loading to streams and lakes, including Lake Erie. The strategy was submitted to U.S. EPA-Region 5 in 2013. Ohio EPA is currently updating the strategy to address gaps identified through U.S. EPA's review. The strategy and more information about the effort are available at http://www.epa.ohio.gov/dsw/wqs/NutrientReduction.aspx.
- 2. **GLRI Demonstration and Nutrient Reduction Projects:** Nine grants totaling over \$12 million were awarded to Ohio. Highlights include: first saturated buffer installed in Ohio; 53 controlled drainage structures installed; 52 whole farm conservation plans developed; 7,500 acres of cover crops planted; and 29 storm water, wetland and stream restoration projects in Cuyahoga County.
- 3. Ohio Senate Bill 1: This bill, effective July 3, 2015, requires major public-owned treatment works (POTWs) to conduct technical and financial capability studies to achieve 1.0 mg/L total phosphorus; establishes regulations for fertilizer or manure application for persons in the western basin⁹; designates the director of Ohio EPA as coordinator of harmful algae management and response and requires the director to implement actions that protect against cyanobacteria in the western basin and public water supplies; prohibits the director of Ohio EPA from issuing permits for sludge management that allow placement of sewage sludge on frozen ground; and prohibits the deposit of dredged material in Lake Erie on or after July 1, 2020, with some exceptions.

⁹ "Western basin" is defined in this Senate Bill as consisting of the following 11 watersheds: Ottawa watershed, HUC 04100001; River Raisin watershed, HUC 04100002; St. Joseph watershed, HUC 04100003; St. Mary's watershed, HUC 04100004; Upper Maumee watershed, HUC 04100005; Tiffin watershed, HUC 04100006; Auglaize watershed, HUC 04100007; Blanchard watershed, HUC 04100008; Lower Maumee watershed, HUC 04100009; Cedar-Portage watershed, HUC 04100010; and Sandusky watershed, HUC 04100011.

- 4. **Ohio Senate Bill 150**: This bill, effective August 21, 2014, requires, among other things, that beginning September 31, 2017, fertilizer applicators must be certified and educated on the handling and application of fertilizer; and authorizes a person who owns or operates agricultural land to develop a voluntary nutrient management plan or request that one be developed for him or her.
- 5. **Ohio HB 64**: This bill, effective June 30, 2015, requires the development of a biennial report by spring 2016 on mass loading of nutrients delivered to Lake Erie and the Ohio River from Ohio's point and nonpoint sources. A summary of the bill is available at https://www.legislature.ohio.gov/legislation/legislation-summary?id=GA131-HB-64.
- 6. **Ohio Clean Lakes Initiative:** The Ohio General Assembly provided more than \$3.5 million for projects to reduce nutrient runoff in the Western Lake Erie Basin.
- 7. **Healthy Lake Erie Initiative**: The Ohio General Assembly provided \$10 million to the Healthy Lake Erie Initiative to reduce the open lake placement of dredge material into Lake Erie. These sediments often contain high levels of nutrients or other contaminants so finding alternative use or disposal options is a priority.
- 8. Targeted Funding to Ohio Drinking Water and WWTPs: More than \$150 million was made available starting in 2014 to help public water systems keep drinking water safe and to help wastewater treatment plants reduce the amount of phosphorus they discharge into the Lake Erie watershed. As of June 2016, over \$61 million had been awarded for this work and most of the remainder has been allocated for specific projects.
- 9. **Directors' Agricultural Nutrients and Water Quality Working Group:** This is a collaborative working group that consists of participants from Ohio EPA, ODA and ODNR. The group's report contains a number of recommendations to be implemented during the next several years. For example, the report recommends ways for farmers to better manage fertilizers and animal manure and also provides the state with the means to assist farmers in the development of nutrient management plans and to exert more regulatory authority over the farmers who are not following the rules. The report is available at http://www.agri.ohio.gov/topnews/waterquality/docs/FINAL_REPORT_03-09-12.pdf.
- 10. **Ohio Lake Erie Phosphorus Task Force Phase 2**: The Task Force, which includes participants from Ohio EPA, ODA and ODNR, originally met back in 2009 and was brought back together in 2012 to build on its previous work and make recommendations for improving water quality in the Lake Erie watershed. The taskforce finalized the latest report in 2014 and it is available at http://lakeerie.ohio.gov/Portals/0/Reports/Task_Force_Report_October_2013.pdf.
- 11. **Ohio Point Source and Urban Runoff Workgroup:** Businesses, municipalities and Ohio EPA came together to initiate the "Point Source and Urban Runoff Workgroup" in 2012 in order to identify actions that can be taken immediately to reduce phosphorus loadings from WWTPs, industrial discharges and urban storm water. The group's full report is available at http://epa.ohio.gov/portals/35/documents/point_source_workgroup_report.pdf.

J4. Summary of Results

The consolidated results of the 2016 analysis are shown in Table J-4 and Figures J-7 through J-9. Compared with past reports, the number of TMDLs continues to rise and the number of units with an "unknown" condition continues to decrease.

Table J-4. Summary of results for each beneficial use¹⁰

Table J-4. Summary of results for each b	Human Health			
	(Fish Contaminants)	Recreation	Aquatic Life	Public Drinking Water Supply
Watershed assessment units				
Not being used for public water supply	0	0	0	1427
Attains	218	153	420	39

¹⁰ Reported using federally-defined categories (see Table J-1), except for two defined by Ohio [category 0 (not being used for public water supply) and subcategory 4n (impaired due to natural condition)]. Other Ohio-defined subcategories are included in federal categories

Figure J-7. Summary of 2016 IR results for watershed AUs by beneficial use.

Figure J-8. Summary of 2016 IR results for large river AUs by beneficial use.

Figure J-9. Summary of 2016 results by AU type.

J5. Changes to the 2014 303(d) List

Federal regulations require a demonstration of good cause for not including water bodies on the Section 303(d) list that were included on previous 303(d) lists (40 CFR 130.7(b)(6)(iv)). Over time, U.S. EPA has modified the wording of reasons for delisting in guidance (U.S. EPA 2005, 2006, 2009, 2011, 2013) to be used in preparing this report. Ohio is removing 132 AUs and adding 329 AUs based on one of these three reasons:

- Flaw in original listing: reason noted for each change. Most of the changes are for the aquatic life use and are due to a reevaluation of the AU and lack of data (sampling and historical) in order to make an assessment. In one instance, an AU (Chapman Creek 05080001 16 06) was assigned a Category 5 ranking under "flaw in original listing" because the impairment was documented due to an unknown cause and source even though a TMDL had been completed and approved by U.S. EPA
- New data: the assessment and interpretation of more recent data
- TMDL approved¹¹: approval by U.S. EPA of a TMDL.

Table J-5 summarizes the number of watershed, large river and Lake Erie shoreline AUs being removed from the 2014 303(d) list. Table J-6 and Figure J-6 summarize the number of AUs being changed for each of the three reasons. Each AU removed or added for each reason is presented in Tables J-7 through J-12.

Table J-5. Number of AUs removed from or added to the 303(d) list.

		Number of	AUs	
	Watershed	Large River	Lake Erie	Total
Delistings [Remove from 303(d) list]				
Human Health (fish tissue)	15	0	0	15
Recreation	37	1	0	38
Aquatic Life	76	2	0	78

¹¹ While Ohio has completed these TMDLs and they were approved by U.S. EPA, in March 2015 in *Fairfield Cty. Bd. of Commrs. v. Nally,* 143 Ohio St. 3d 93, 2015-Ohio-991, the Ohio Supreme Court determined that "A TMDL established by Ohio EPA pursuant to the Clean Water Act is a rule that is subject to the requirements of R.C. Chapter 119, the Ohio Administrative Procedure Act." See Section C (page C-17) for more details.

J6. Schedule for TMDL Work

Once waters are assessed and the impaired waters are prioritized, the next step is to determine a schedule to address the monitoring needs of all waters and restoration needs (including TMDLs) of the impaired ones. Various factors must be considered, including Ohio's ongoing TMDL work; the process identified to do TMDLs; the monitoring strategy; and the resources available for the work.

Over the past few years, TMDL projects transitioned from the old HUC 11-scale watersheds to the new, smaller HUC 12-scale watersheds. Through 2009, TMDLs were completed using the HUC 11-scale AUs. Projects submitted for approval after April 1, 2010, reflect the new HUC 12-size units. Tables in Section J4 and the TMDL status map in Section K reflect current information based on the HUC 12 units.

J6.1. Ohio TMDL Status

Ohio EPA is currently working on TMDLs in about 40 project areas and has approved TMDLs in about 50 project areas. After 2016, only one project area will remain to be assessed using our current survey approach (i.e., the Whitewater River area in southwest Ohio). Table J-13 summarizes Ohio TMDLs approved by U.S. EPA at the 11-digit HUC level. Table J-14 summarizes Ohio TMDLs approved by U.S. EPA at the 12-digit HUC level. It must be noted that the Ohio Supreme Court decision arguably invalidates the approved TMDLs established by Ohio EPA, as noted in Section C on page C-17 of this report. Ohio EPA is evaluating alternatives for addressing both past and future TMDLs.

J6.2. Long-Term Schedules for Monitoring and TMDLs

Ohio's rotating basin approach (see Section D) provides a foundation for scheduling monitoring and TMDL projects. The assessment methodology allows that, generally, aquatic life use monitoring data up to 10 years old may be considered in judging AUs, so it follows that each AU must be monitored at least once every 10 years to maintain coverage. However, resources to maintain this pace are no longer available; cycling through the entire basin rotation would take about 15 to 20 years at current resource levels.

In an effort to maintain the monitoring and TMDL schedule, Ohio EPA is committed to researching and pursuing additional resources, both in terms of funding and partnering opportunities. Ohio's credible data law (ORC 6111.52) requires level three credible data to establish a TMDL and to identify, list and delist waters of the state for purposes of §303(d).

A map illustrating the long-term monitoring schedule is included in Section K. Detailed information for each AU is also available on the IR web site (http://epa.ohio.gov/dsw/tmdl/OhioIntegratedReport.aspx).

J6.3 Short-Term Schedule for TMDL Development

Ohio EPA has only scheduled a few TMDL projects during the next two years, as indicated in Table J-15. Because Ohio's TMDL process begins with a watershed assessment, all TMDLs to be completed in the next two years are already in progress. Since the process for finalizing TMDLs is uncertain following the Ohio Supreme Court decision (see Section C, page C-17), Ohio EPA does not anticipate submitting very many TMDLs to U.S. EPA for approval in the short term. However, the agency is still committed to restoring water quality and will be exploring other alternatives to this end in both the short and long term, as outlined in the 303(d) Vision discussion in Section C8 of this report.

Table J-13. Ohio TMDLs¹³ approved by U.S. EPA at the 11-digit hydrologic unit scale¹⁴.

AU Code	AU Name	U.S. EPA Approval Date	Pollutants Allocated, per U.S. EPA ¹⁵
04110002 020	Cuyahoga River (below Black Brook to below Breakneck Creek)		
04110002 030	Cuyahoga River (below Breakneck Creek to below Little Cuyahoga River)	10/11/2000	dissolved oxygen
04110001 070	Rocky River (below West Br. to Lake Erie [including East Br.] and Lake Erie tribs [above Porter Cr to above Cuyahoga R]): Plum Creek	12/04/2001	phosphorus, nitrogen
05090202010	Little Miami River (headwaters to above Massies Creek)		
05090202 020	Little Miami River (above Massies Creek to below Beaver Creek)	07/00/0000	
05090202030	Little Miami River (below Beaver Creek of above Caesar Creek)	07/02/2002 05/13/2003	phosphorus, sediment
05090202 040	Anderson Fork Caesar Creek		
05090202050	Caesar Creek (except Anderson Fork)		
05060001 060	Bokes Creek (Scioto River above Bokes Creek to above Mill Creek)	09/27/2002 07/31/2003	phosphorus, sediment

¹³ One or more AUs may be included in a TMDL report; the determination is made on a project-by-project basis, at the discretion of Ohio EPA.

¹⁴ While Ohio has completed these TMDLs and they were approved by U.S. EPA, in March 2015 in *Fairfield Cty. Bd. of Commrs. v. Nally,* 143 Ohio St. 3d 93, 2015-Ohio-991, the Ohio Supreme Court determined that "A TMDL established by Ohio EPA pursuant to the Clean Water Act is a rule that is subject to the requirements of R.C. Chapter 119, the Ohio Administrative Procedure Act." See Section C (page C-17) for more details.

¹⁵ The TMDL goal is restoration of the designated use through the attainment of applicable criteria. Pollutants listed here were specifically recognized in U.S. EPA decision documents. TMDL reports typically include such parameters for targeting, pollutant load characterization and measuring interim progress and may explore other indicators of watershed condition.

AU Code	AU Name	U.S. EPA Approval Date	Pollutants Allocated, per U.S. EPA ¹⁵

05090202 08 01 – 04	Turtle Creek-Little Miami River		chemical oxygen demand,
05090202 09 01 – 03	O'Bannon Creek-Little Miami River	3/28/2011	sediment, total
05090202 14 01 – 06	Sycamore Creek-Little Miami River		suspended solids,
05090202 90 01	Little Miami River Mainstem (Caesar Creek to O'Bannon Creek)		carbonaceous biochemical
05090202 90 02	Little Miami River Mainstem (O'Bannon Creek to Ohio River)		oxygen demand
05040004 06 01 – 06	Salt Creek (Muskingum River watershed)	6/6/2011	E. coli

¹⁶ One or more AUs may be included in a TMDL report. The determination is made on a project-by- project basis, at the discretion of Ohio EPA.

¹⁷ While Ohio has completed these TMDLs and they were approved by U.S. EPA, in March 2015 in *Fairfield Cty. Bd. of Commrs. v. Nally*, 143 Ohio St. 3d 93, 2015-Ohio-991, the Ohio Supreme Court determined that "A TMDL established by Ohio EPA pursuant to the Clean Water Act is a rule that is subject to the requirements of R.C. Chapter 119, the Ohio Administrative Procedure Act." See Section C (page C-17) for more details.

¹⁸ The TMDL goal is restoration of the designated use through the attainment of applicable criteria; pollutants listed here were specifically recognized in U.S. EPA decision documents. TMDL reports typically include such parameters for targeting, pollutant load characterization and measuring interim progress and may explore other indicators of watershed condition.

¹⁹ The TMDL was revised for one pollutant.

Summary Tables of Waterbody Conditions; Lists of Prioritized Impaired Waters; and Monitoring and TMDL Schedules Case: 3:17-cv-01514-JGC Doc #: 1-12 Filed: 07/18/17 387 of 601. PageID #: 1384

Section L contains tables showing the 303(d) listing details for each of the assessment unit types and is divided into five sections as follows:

- 1) Section L1: Status of Watershed Assessment Units
- 2) Section L2: Status of Large River Assessment Units
- 3) Section L3: Status of Lake Erie Assessment Units
- 4) Section L4: Section 303(d) List of Prioritized Impaired Waters
- 5) Section L5: Category 4B demonstrations contained in approved Ohio TMDLs to date

In Sections L1 through L4, there are four columns labeled, in order: "Human Health," "Recreation," "Aquatic Life" and "PDW Supply." These four columns represent each beneficial use included in the 303(d) list of impaired waters and the numbers in the columns represent the category for that assessment unit for that beneficial use. Table L-1 (below) defines that categories and subcategories assigned to each use.

Table L-1. Category definitions for the 2016 Integrated Report and 303(d) list

Categ	ory ¹		tegory
0	No waters currently utilized for water supp	oly	
1	Use attaining	d	TMDL complete; new data show the AU is attaining water quality standards
		h	Historical data
		t	TMDL complete at 11-digit hydrologic unit code (HUC) scale; AU is attaining water quality standards at 12-HUC scale
		Х	Retained from 2008 IR
2	Not applicable in Ohio system		
3	Use attainment unknown	h	Historical data
		i	Insufficient data
		t	TMDL complete at 11-HUC scale; there may be no or not enough data to assess this assessment unit at the 12-HUC scale
		Х	Retained from 2008 IR
4	Impaired; TMDL not needed	А	TMDL complete ²
		В	Other required control measures will result in attainment of use
		С	Not a pollutant
		h	Historical data
		n	Natural causes and sources
		Х	Retained from 2008 IR
5	Impaired; TMDL needed	М	Mercury
		alt	Alternative restoration approaches
		d	TMDL complete; new data show the AU is not attaining water quality standards
		h	Historical data
		Х	Retained from 2008 IR

¹ Shading indicates categories defined by U.S. EPA; additional categories and subcategories are defined by Ohio EPA.

² While Ohio has completed these TMDLs and they were approved by U.S. EPA, in March 2015 in *Fairfield Cty. Bd. of Commrs. v. Nally*, 143 Ohio St. 3d 93, 2015-Ohio-991, the Ohio Supreme Court determined that "A TMDL established by Ohio EPA pursuant to the Clean Water Act is a rule that is subject to the requirements of R.C. Chapter 119, the Ohio Administrative Procedure Act." See Section C (page C-17) for more details.

L5. Category 4B Demonstrations Contained in Approved Ohio TMDLs to Date

Ohio EPA expects to use the 4B alternative in conjunction with total maximum daily loads (TMDLs) to efficiently address water quality impairments in the future. Though the 4B category does not currently appear in Ohio's 303(d) list, the concept of a 4B alternative is used to address certain impairments. Because Ohio EPA typically completes TMDLs on a watershed basis, it makes sense to include discussion of 4B demonstrations in TMDL reports as approval of a TMDL is sought, then to report on progress in Integrated Reports. As new 4B demonstrations accumulate, they will be collected into future Integrated Reports. Progress on individual 4B projects will be reported in subsequent Integrated Reports until the impairment is resolved or until a decision is made that the 4B will not be sufficient to address the impairment and a TMDL is scheduled.

This section presents the 4B discussions as they appeared in the respective TMDL reports, with updates on current status. Text that is not original to this report appears in a lighter text color; plans and dates are not changed from the original so some text may appear to be outdated. The table below shows the locations of the original 4B demonstrations as included with TMDL reports and where updates are included in this report.

Name of Watershed	Location of 4B in Report	Date of TMDL Approval	Updated Sections in 2016 IR	Page Number
Salt Creek Watershed (Scioto River basin)	Appendix D	8/12/2009	5.1.1.3	L5-6
White Oak Creek Watershed	Appendix H	2/25/2010	5.2.1.3	L5-9
Twin Creek Watershed	Appendix B	3/4/2010	5.2.2.3	L5-13
Walnut Creek Watershed	Appendix B	5/4/2010	5.2.3.3	L5-18
Great Miami River (upper) Watershed	Appendix E	3/26/2012	5.3.1.2	L5-28

L5.1 Projects included in the 2010 Integrated Report

Prior to the 2010 Integrated Report, Ohio submitted one 4B alternative as part of an approved TMDL, for Salt Lick Creek (Salt Creek Watershed TMDL Report). Together with TMDLs approved for other impairments to the aquatic life use, the 4B work should bring Little Salt Creek into attainment with water quality standards.

L5.1.1 Salt Lick Creek (Salt Creek, Scioto River Watershed)

The main stem of Salt Lick Creek (in assessment unit 05060002 090¹) was identified as impaired by nutrients, specifically total phosphorus, during the field sampling in 2005. Upstream of the wastewater treatment plant (WWTP) in the City of Jackson, the stream was in attainment of its aquatic life use. Downstream of the treatment plant, the aquatic life in the stream was impaired. Analysis of nutrients upstream and downstream of the WWTP indicated that the large increase in nutrients from the WWTP was likely the largest contributor to impairment in this portion of the stream. Prompt action was taken to address this through the National Pollutant Discharge Elimination System (NPDES) permit renewal.

¹ The Salt Creek TMDL was approved using the larger, HUC 11-size assessment units. The 4B actions will affect two HUC 12-size assessment units: 05060002 08 01 and 08 03.

Ohio EPA proposes that this impairment be handled through a category 4B alternative instead of a TMDL. Further details are discussed below. Additional information is available in the main text of the TMDL and in the forthcoming biological and water quality study publication.

Identification of segment and statement of problem causing the impairment

The cause of aquatic life use impairment was identified to be a failing sewage collection system, poor nutrient (specifically phosphorus) removal from the City of Jackson WWTP and by-passes of treatment at the WWTP. In-stream levels for phosphorus at the two uppermost Salt Lick Creek sampling locations ranged from 0.01 mg/L to 0.11 mg/L. The sample location immediately downstream from the City of Jackson's WWTP ranged from 1.37 mg/L to 4.11 mg/L. The WWTP was not sampled for chemistry during the survey. At the time of the survey the City of Jackson was not required to sample for nor had a limit for phosphorus. Ammonia results from stream samples and WWTP sample results show very little nutrient contribution from the WWTP. Attachment 1 shows that the biology scores decrease downstream of the City of Jackson's WWTP discharge.

OAC 3745-01-07, Table 7-11 states in footnote c: "Total phosphorus as P shall be limited to the extent necessary to prevent nuisance growths of algae, weeds, and slimes that result in a violation of the water quality criteria set forth in paragraph (E) of rule 3745-1-04 of the Administrative Code or, for public water supplies, that result in taste or odor problems. In areas where such nuisance growths exist, phosphorus discharges from point sources determined significant by the director shall not exceed a daily average of one milligram per liter as total P, or such stricter requirements as may be imposed by the director in accordance with the international joint commission (United States-Canada agreement)." During initial investigation of a fish kill on Salt Lick Creek in 2003, Ohio EPA observed excessive white stringy slime fungus growing at the City of Jackson's WWTP discharge point.

Poor sanitary sewer operation and maintenance leading to sewer breaks and overflows, high nutrient discharges from WWTP and by-passes at the WWTP have all contributed to poor aquatic performance. No stream flow was taken during sampling; thus loadings are not available. However, in-stream phosphorus concentrations increased from 0.06 mg/L upstream of the WWTP to 2.42 mg/L immediately downstream of the WWTP.

Description of pollution controls and how they will achieve water quality standards

The City of Jackson operates a sewer collection system and a wastewater treatment facility that handles domestic and industrial sewage for a population of about 6,000. Page 14 of the Jackson WWTP Fact Sheet (FS) states that phosphorus limits are required (see FS

http://www.epa.state.oh.us/dsw/permits/doc/0PD00008.fs.pdf². The City of Jackson is required by its NPDES permit (OH0020834—see permit http://www.epa.state.oh.us/dsw/permits/doc/0PD00008.pdf to achieve a limit of 1.0 mg/L (monthly average) for phosphorus and eliminate all by-passes at the WWTP by August 1, 2009. The City of J a c k s o n is required, under Consent Order (Case No. 07C1V190 – see http://www.epa.state.oh.us/dsw/enforcement/JacksonCO2007.pdf ⁴to eliminate all sewer overflows by October 1, 2009; operate and maintain sewer collection system by implementing a

³ This Web page has changed to http://www.app.epa.ohio.gov/dsw/permits/doc/0PD00008.pdf.

⁴ This Web page has changed to http://www.epa.ohio.gov/portals/35/enforcement/JacksonCO2007.pdf.

Capacity Management, Operation and Maintenance plan by December 31, 2008; develop an Overflow Emergency Response Plan by July 1, 2008, that identifies measures to protect public health and the environment; separate all storm sewers from sanitary sewers by April 1, 2009; and if problems persist then the City of Jackson must develop a System Evaluation and Capacity Assurance Plan to provide adequate capacity to convey and treat base and peak flows for all parts of Jackson sewer system by April 1, 2011. If the impairment continues after the 1 mg/L phosphorus limit is achieved and before the NPDES permit expires, then the limit can be lowered per OAC 3745-01-07.

Point source loadings for phosphorus associated with proper operation of the systems should be no more than 14.3 kg/day. There are no known nonpoint sources.

An estimate or projection of the time when WQS will be met

After August 1, 2009 the phosphorus limit should be met and by-passing treatment should be eliminated. The water body is expected to respond to the load reduction, but recovery will not be instantaneous. Ohio EPA will monitor the stream for recovery.

Schedule for implementing pollution controls

The City of Jackson is currently in the process of a WWTP expansion that will include advanced treatment, ability to handle higher flows and eliminate overflows and by-passes by August 1, 2009. The City of Jackson is required to provide annual status reports to Ohio EPA every August first.

If they are unsuccessful, Ohio EPA will hold the City in contempt of the consent order and initiate enforcement on non-compliance with the NPDES permit schedule and effluent limits.

Ohio EPA has approved the NPDES permit with compliance schedule to meet a phosphorus limit of 1.0 mg/L.

Monitoring plan to track effectiveness of pollution controls

The City of Jackson is required to submit an annual status report to Ohio EPA every August first and submit monthly Discharge Monitoring Reports for effluent quality from the WWTP.

Prior to the NPDES permit expiration on January 31, 2011, Ohio EPA will sample the impaired section of Salt Lick Creek for chemistry, fish and macroinvertebrates (summer of 2010). The chemistry will be sampled at four locations and five sampling events will be completed. The fish will be sampled at four locations with two passes each. The macroinvertebrates will be sampled at four locations once per standard protocols. The sampling will take place during the summer/fall sampling season with analysis by Ohio EPA's laboratory and reporting to Southeast District Office (SEDO⁵) DSW Manager, DSW NPDES Manager, and TMDL Coordination.

The City of Jackson, SEDO Water Quality (WQ) staff and Ecological Assessment Section staff will do the monitoring.

Commitment to revise pollution controls, as necessary

Pollution controls will be revised by SEDO WQ and NPDES staff, supported by SEDO DSW Manager. Ohio EPA will report on the progress of any approved 4B in future 303(d) lists.

Attachment 1

Historical trend for IBI and MIwb for Salt Lick Creek mainstem.

L5.1.1.1 First Report on Salt Lick Creek 4B Demonstration (2012 Integrated Report)

In 2011, four sites on Salt Lick Creek were sampled for macroinvertebrates and three sites for fish. All three fish sites sampled (upstream from the Jackson WWTP at river mile 22.6; immediately downstream from the Jackson WWTP effluent at river mile 22.0; and further downstream at river mile 18.2) appear to be doing well but have not yet been completely analyzed. Macroinvertebrate samples are still being analyzed. Aquatic life attainment status will be reported in the 2014 IR. When available, data will be reported on Ohio EPA's Interactive Maps web site (http://www.epa.ohio.gov/dsw/qis/index.aspx).

L5.1.1.2 Second Report on Salt Lick Creek 4B Demonstration (2014 Integrated Report)

In 2011, biological and habitat sampling was conducted in Salt Lick Creek upstream from, near field to, and downstream from the Jackson WWTP, which has had past issues with collection system failures, and the old Jackson city landfill; impacts on resource quality and impairment of the designated WWH aquatic life use were documented in a prior 2004 survey. Four sites spanning the previously impaired reach were sampled for macroinvertebrates and three sites for fish; results and attainment status are shown in the table below. At the three sites where both fish and macroinvertebrates were collected, full attainment of the WWH use was realized. At the fourth site where only macroinvertebrates were collected, a community assessed as marginally good achieved ecoregional WWH expectations.

River Mile	Stream Name	IBI	Mlwb	ICI	Macroinvertebrate Narrative	QHEI	Attainment Status
22.55	Salt Lick Creek at Jackson @ High St.	46	8.98		Marginally good	56.00	Full
21.90	Salt Lick Creek dst. Jackson WWTP	44	8.20	36		73.50	Full
20.30	Salt Lick Creek adj. landfill	-	-	-	Marginally good		-
18.12	Salt Lick Creek east of Lake Katherine @ Rock Run Rd.	46	8.31	50		76.80	Full

L5.1.1.3 Third Report on Salt Lick Creek 4B Demonstration (2016 Integrated Report)

The 2011 biological and habitat data documented full aquatic life use recovery at the previously impaired sites. The impairment is considered resolved. Ohio EPA reports progress on individual 4B projects until the impairment is resolved; progress on the Salt Lick Creek 4B will not be recorded in future Integrated Reports.

L5.2 Projects included in the 2012 Integrated Report

After completion of the 2010 Integrated Report and before completion of the 2014 Integrated Report, Ohio submitted three 4B alternatives as part of approved TMDLs: Town Run (White Oak Creek Watershed TMDL Report); Twin Creek (Twin Creek Watershed TMDL Report); and Sycamore Creek (Walnut Creek Watershed TMDL Report). Together with TMDLs approved for other impairments to the aquatic life use, the 4B work should bring the streams into attainment with water quality standards.

L5.2.1 Town Run (White Oak Creek Watershed)

Impairment of biological water quality standards and high ammonia concentrations have been measured in Town Run, a tributary to White Oak Creek at river mile (RM) 6.95. Town Run is a high gradient bedrock substrate headwater stream that is fed by ground water. The City of Georgetown WWTP discharges to Town Run at RM 0.80. The biological impairment and high ammonia concentrations are resulting from the Georgetown WWTP effluent discharge. Ohio EPA proposes that this impairment be handled through a category 4B alternative instead of a total maximum daily load (TMDL). Further details are discussed below. Additional information is available in the main text of the TMDL and in the biological and water quality study publication.

Ohio EPA is addressing the phosphorus and nitrate-nitrite impairments via a TMDL analysis expected to be completed in 2009.

Identification of segment and statement of problem causing the impairment

Ohio EPA measured the water quality in the White Oak Creek watershed in 2006, collecting biological, chemical and physical data. The following paragraph from Ohio EPA's water quality report summarizes the problems observed in Town Run:

"Biological sampling in Town Run (RM 0.9 in 2008) found a marginally good community of macroinvertebrates and a reproducing population of the cold water indicator two-lined salamander upstream from the Georgetown WWTP discharge (RM 0.80). Downstream from the WWTP discharge (RM 0.7 in 2008) the macroinvertebrate community was very poor and there was no observed reproduction of the two-lined salamander. High concentrations of Ammonia-N (median of 3.24 mg/L), Phosphorus-T (median of 3.04 mg/L), and Nitrate-Nitrite-N (median of 6.39 mg/L) were recorded downstream from the WWTP discharge in 2006."

(http://www.epa.ohio.gov/portals/35/documents/WhiteOakCreekTSD2006.pdf, p. 9)

During Ohio EPA's water quality survey of the White Oak Creek watershed in 2006, five sets of chemical samples were collected at sites upstream and downstream of the Georgetown WWTP. Upstream of the WWTP, the median value for ammonia was 0.05 mg/L. Downstream of the WWTP, the ammonia value was 3.24 mg/L. The median ammonia value of the Georgetown WWTP effluent was 4.07 mg/L.

Biological impact was significant, resulting in a listing on the 303(d) list. Upstream of the WWTP, Town Run is fully attaining the Aquatic Life Use, but downstream of the WWTP the use is not attained.

Description of pollution controls and how they will achieve water quality standards

Town Run is effluent-dominated downstream from the Georgetown WWTP. The drainage area upstream of the WWTP discharge is only 1.3 square miles.

The median flow of the Georgetown WWTP from 2002-2006 was 0.47 million gallons per day (MGD) with 23.8 percent (420/1764) of the flow dates being over the facility's design capacity of 0.80 MGD.

The critical period for ammonia in such an effluent-dominated stream is late summer when ambient temperatures are highest and stream flows are lowest. Calculating a load to meet water quality standards during the summer is protective of other time periods. A winter load is calculated to meet the

needs of Ohio EPA's permitting program.

By reducing the effluent concentration of ammonia from Georgetown, water quality standards for ammonia and the Aquatic Life Use in Town Run are expected to be met.

The nonpoint source load is zero because of the limited drainage area above the WWTP's discharge point. At the critical condition, no upstream flow would be expected.

Loadings for point sources can be calculated using a mass-balance equation. In this case, since upstream flow equals zero, the allocation for the Georgetown WWTP is equal to the water quality standards (WQS). The ammonia WQS for exceptional warmwater habitat (EWH)/coldwater habitat (CWH) is 0.6 mg/L during summer and 1.93 mg/L during winter.

Thus, the load allocated to the Georgetown WWTP = (WQS) x (Effluent flow) x (conversion factor):

Summer: 0.6 mg/L x 0.8 MGD x (factor) = 1.82 kg/dayWinter: 1.93 mg/L x 0.8 MGD x (factor) = 5.85 kg/day

An estimate or projection of the time when WQS will be met

After the Georgetown WWTP meets the new ammonia permit limit (by November 2014), the ammonia limit should be met. The water body is expected to respond to the load reduction, but recovery will not be instantaneous. Ohio EPA will monitor the stream for recovery.

Schedule for implementing pollution controls

The Georgetown NPDES permit expires on February 28, 2010. Prior to that date, Ohio EPA will issue a new permit with a 30-day average limit on effluent ammonia of 0.6 mg/L (summer) and 1.93 mg/L (winter).

Officials at the Georgetown WWTP have contracted with an engineering firm and they have produced a plan to upgrade the WWTP to achieve compliance with the new ammonia limits. The WWTP upgrade will be completed by November 2014.

Ohio EPA will monitor Georgetown's progress toward meeting the permit limits by following up on the construction activity and reviewing monthly effluent reports.

Monitoring plan to track effectiveness of pollution controls

As a part of its NPDES permit, the Georgetown WWTP measures and reports ammonia concentrations in its effluent and in Town Run upstream and downstream of its discharge point. The sampling will be conducted twice per week and reported monthly. The facility's monthly discharge monitoring reports are reviewed by permit staff in Ohio EPA's Southwest District Office. Ohio EPA staff will also conduct facility inspections approximately annually.

After the Georgetown ammonia reductions have been in place for at least one year, Ohio EPA will revisit the area to determine if progress toward meeting the Aquatic Life Use is being made. This work would follow Ohio EPA's protocol for sampling the aquatic biology and chemistry.

Commitment to revise pollution controls, as necessary

The SWDO surface water manager will initiate a reexamination of the implementation strategy if significant progress is not being made by the end of the next NPDES permit cycle for Georgetown.

Ohio EPA will report on the progress of any approved 4B in future 303(d) lists.

L6.2.1.1 First Report on Town Run 4B Demonstration (2012 Integrated Report)

A permit was issued to the Georgetown WWTP effective on September 1, 2010. Final effluent limitations for ammonia are 0.60 mg/L (summer monthly average) and 1.76 mg/L (winter monthly average). Those limits must be met beginning on September 1, 2014.

L6.2.1.2 Second Report on Town Run 4B Demonstration (2014 Integrated Report)

The Georgetown WWTP is under construction in fall 2013 to make improvements to meet the new nitrogen-ammonia and total phosphorus limits. The upgrade is scheduled to be completed by September 1, 2014, but upgrades are currently ahead of schedule. Follow-up sampling will take place in 2015 or 2016, so results will likely be available for the 2018 Integrated Report.

L5.2.1.3 Third Report on Town Run 4B Demonstration (2016 Integrated Report)

The Georgetown WWTP did not complete its scheduled upgrades by September 1, 2014, due to contractor issues. The WWTP upgrades were completed on July 1, 2015, and all treatment improvements should help meet the nitrogen-ammonia and total phosphorus limits. Follow up sampling will take place in 2016.

L5.2.2 Twin Creek

The main stem of Twin Creek (in assessment unit 05080002 030) was identified as impaired by total phosphorus during the field sampling in 2005; organic enrichment was later added to the list of causes upon further investigation in the summer of 2009. Upstream of the WWTP in the City of Lewisburg, the stream was in attainment of its aquatic life use. Downstream of the treatment plant, the aquatic life in the stream was partially supporting the use. The City of Lewisburg WWTP discharges to Twin Creek at river mile (RM) 35.2. No impairment to Twin Creek upstream of Lewisburg or downstream at RM 33.6 was found. The biological impairment (between the WWTP and RM 33.6) is resulting from the Lewisburg WWTP effluent discharge. Ohio EPA proposes that this impairment be handled through a category 4B alternative instead of a total maximum daily load (TMDL). Further details are discussed below. Additional information is available in the main text of the TMDL and in the forthcoming biological and water quality study publication.

Identification of segment and statement of problem causing the impairment

An Invertebrate Community Index (ICI) of 38 was garnered at RM 34.9, which was below the Exceptional Warmwater Habitat (EWH) criterion. In 2005, excessive phosphorus due to either the Lewisburg WWTP, herbicide runoff from an upstream municipal park, or contaminated storm water was considered potential contributors to this impairment. However, new information obtained during an inspection of the Lewisburg WWTP in September 2009 revealed that biological solids were being discharged directly

into Twin Creek from the wastewater plant. Gray and brown sewage sludge was observed in Twin Creek from Lewisburg's outfall downstream to at least the Salem Road Bridge, with thick algal mats coating the heaviest deposits. Black anoxic muck was also observed under many of the substrates. Because of these new findings, it is apparent that nutrient enrichment was a secondary cause of impairment to Twin Creek at RM 34.9. Organic enrichment attributable to improper solids management at the Lewisburg WWTP is now considered the primary cause of impairment to the macroinvertebrate community at RM 34.9.

Further information regarding the 2005 findings is available in the Biological and Water Quality Study of Twin Creek and Select Tributaries 2005, available on Ohio EPA web site (http://www.epa.ohio.gov/portals/35/documents/TwinCreek2007TSD.pdf). This report will be amended to reflect the 2009 observations.

Ohio EPA included nutrient enrichment for this assessment unit in the 2008 Integrated Report (303(d) list), available at (http://www.epa.ohio.gov/dsw/tmdl/2008IntReport/2008OhioIntegratedReport.aspx). The 2010 Integrated Report will add organic enrichment as an impairment cause for this assessment unit.

The primary issue with the Lewisburg WWTP is that biological solids or sludge is making its way into the stream resulting in the stream conditions described above. Sludge in the creek will contribute nutrients (phosphorus) and bacteria as well as smothering the substrate. Biological solids are largely made up of sewage treatment micro-organisms, living and dead. Micro-organisms contain phosphorus compounds (e.g., nucleic acids, ADP, ATP). Biosolids from WWTPs are frequently used as an agricultural soil amendment with some fertilizer value. Lewisburg's 2008 annual sewage sludge report included the following analyses results (on a dry weight basis): TKN = 35,000 mg/Kg; $NH_3-N = 8590 \text{ mg/Kg}$; and phosphorus = 15,900 mg/Kg.

This information demonstrates there is a nutrient content to Lewisburg's sludge.

In September 2009 there appeared to be both structural and operational problems. Clarified water was overflowing only portions of the clarifier weirs; this may have been caused by the weirs not being level and sections of the weir being clogged with algae. The net result was that the clarifiers were being short circuited. Compounding the problem was the fact that Lewisburg was not wasting sufficient amounts of sludge from the clarifiers to the sludge digesters. This resulted in old sludge denitrifying and floating to the surface of the clarifiers, which was then discharged to Twin Creek. Plant operating logs also documented difficulty in balancing flow between the two clarifiers during rain, which compromised clarifier performance still further. The appearance of the aeration tanks indicated that the mixed liquor suspended solids were being maintained at higher levels than necessary and that the biological solids in the tank were old.

Description of pollution controls and how they will achieve water quality standards

The Village of Lewisburg operates a sewer collection system and a wastewater treatment facility that handles domestic and industrial sewage for a population of about 1,800. The Lewisburg WWTP holds a NPDES permit (1PB00019*HD).

Lewisburg has been reporting substantial compliance with its NPDES effluent limits over the life of the current permit. Ohio EPA now believes that compositing effluent samples using multiple grab samples

(as allowed by the NPDES permit) did not provide a true reflection of effluent quality. Recent inspections have also revealed quality control issues with the sampling and analyses, casting doubt on the reported effluent data.

Lewisburg has been required in inspection reports and Notices of Violation to take actions to eliminate the problems resulting in discharge of solids to Twin Creek. The Village has since utilized the assistance of Ohio EPA's Compliance Assistance Unit and has engaged an engineering firm that is reviewing plant operations. Lewisburg began implementing changes recommended by the Ohio EPA's Compliance Assistance Unit in November 2009.

Ohio EPA anticipates that the operational problems contributing to the discharge of solids can be resolved well before the NPDES permit is renewed in April 2010. Ohio EPA NPDES permits staff from the Southwest District office will closely monitor operational changes.

The draft renewal of the Lewisburg WWTP NPDES permit, (scheduled for issuance April 1, 2010) contains additional requirements that will address the impairment in Twin Creek downstream of the WWTP discharge. Ohio EPA intends to revisit the Twin Creek sampling sites in Lewisburg in September 2011. If the operational improvements have been properly implemented and yet the ICI at RM 34.9 cannot be demonstrated to comply with EWH criteria due to organic enrichment from the WWTP, Lewisburg will be required by a modification to its NPDES permit to comply with a schedule that leads to compliance with an initial total phosphorus limit of 1.0 mg/L by April 2015.

A complicating factor is that Preble County, at the request of the Village of Lewisburg, cleared bank vegetation and removed gravel bars and woody debris from the creek in the vicinity of RM 34.9 during the summer of 2009. This work was done to protect the Knapke Lane bridge pier and reduce bank erosion. It is unlikely that the target ICI score can be attained at that location unless the creek habitat is restored.

A loading analysis to address the organic enrichment impairment is not necessary given the scope of the operational problems at the Lewisburg WWTP and the ability of the facility to correct the problem. Although it is difficult to predict how much of the secondary nutrient enrichment problem is associated with the operational problems, a simple analysis of chemical data provides guidance on point source loading.

The 2005 data collected in Twin Creek by Ohio EPA show a significant change in total phosphorus concentration at the WWTP's entry into the stream. The median in-stream concentration of total phosphorus upstream of Lewisburg's outfall was 0.038 mg/L. The median in-stream concentration downstream of Lewisburg was 0.239 mg/L. The exceptional warmwater habitat (EWH) in-stream target from *Association Between Nutrients, Habitat, and the Aquatic Biota of Ohio Rivers and Streams* is 0.08 mg/L (http://www.epa.ohio.gov/portals/35/documents/assoc_load.pdf).

A simple loading analysis using the five sets of samples collected in 2005 yields the following total phosphorus loads:

Stream capacity (based on 0.08 mg/L target) = 1.303 kg/d Margin of safety (5 percent) = 0.065 kg/d Load allocation (from nonpoint sources) = 0.856 kg/d Wasteload allocation (Lewisburg WWTP) = 0.382 kg/d

A wasteload allocation of 0.382 kg/d equates to an effluent concentration of 0.39 mg/L total phosphorus

at the WWTP's design flow. The 95th percentile of effluent total phosphorus reported by Lewisburg over the current permit is 3.69 mg/L, although there is uncertainty because of concerns with laboratory practices.

Ohio EPA intends to apply an initial phosphorus limit of 1.0 mg/L that would be triggered if fixing the WWTP's operational problems fails to result in attainment of WQS. While the loading analysis results indicate that this limit will not meet the phosphorus target concentration, it does represent a significant (approximately 72 percent) reduction in phosphorus load from the Lewisburg WWTP. This limit should provide enough in-stream nutrient reduction to improve aquatic life while imposing achievable NPDES limits. Any further reduction in effluent limits should be evaluated after this limit is being attained and an evaluation of the biological condition of the stream has been completed.

An estimate or projection of the time when WQS will be met

The next NPDES permit for Lewisburg's WWTP will be issued in 2010. Ohio EPA anticipates that Lewisburg will be able to eliminate the discharge of biosolids to the creek before the permit is renewed. This will significantly reduce the solids and nutrient load to the creek. Ohio EPA expects that the stream will respond to improved operation within two years of making the changes.

Ohio EPA proposes to measure the ICI at RM 34.9 by September 2011. If the ICI does not comply with EWH criterion due to organic enrichment at that time Lewisburg will be given three years to come into compliance with a permit limit for TP of 1.0 mg/L (that is, by April 2015).

Schedule for implementing pollution controls

Any compliance schedule placed in the NPDES permit will allow three years (2012-2015) to implement new controls to reduce TP in effluent if the ICI score is not in attainment by September 2011. It is expected that operational improvements to reduce organic enrichment and, if needed, effluent controls to reduce TP, will sufficiently improve water quality within five years such that the macroinvertebrate community will be able to recover to full attainment.

Monitoring plan to track effectiveness of pollution controls

The City of Lewisburg WWTP is required to submit monthly Discharge Monitoring Reports for effluent quality from the WWTP and upstream and downstream of its discharge point.

The renewed permit will require 24-hour flow composited effluent sampling at Lewisburg, which will provide a much improved picture of effluent quality. The operations assistance provided by Ohio EPA to the WWTP will include attention to quality control issues so that concerns with past facility monitoring will be resolved.

Following Ohio EPA's Permit Guidance, at upstream and downstream stations, pH, dissolved oxygen and temperature will be monitored once per month year round. Total phosphorus, bacteria and ammonianitrogen will be added to both upstream and downstream stations at a frequency of once per month during the summer season.

The facility's monthly discharge monitoring reports are reviewed by permit staff in Ohio EPA's Southwest District Office. Ohio EPA staff will also conduct unannounced facility inspections at least twice annually

until all identified operational and process changes have been completed.

After the Lewisburg operational improvements have been in place for at least one year, Ohio EPA will return to monitor Twin Creek at RM 34.9 by September 2011 to determine if progress toward meeting the Aquatic Life Use is being made. This work would follow Ohio EPA's protocol for sampling the aquatic biology and chemistry. If sufficient progress is not being made, Ohio EPA will evaluate the options available under NPDES authority, including additional operations assistance and enforcement.

Ohio EPA will report progress in its Integrated Report until the impairment has been eliminated.

Commitment to revise pollution controls, as necessary

The SWDO surface water manager will initiate a reexamination of the implementation strategy if significant progress is not being made by the end of the next NPDES permit cycle for Lewisburg.

Ohio EPA will report on the progress of any approved 4B in future 303(d) lists.

L5.2.2.1 First Report on Twin Creek 4B Demonstration (2012 Integrated Report)

Addressing organic solids issues at the Lewisburg WWTP has proven more difficult than originally anticipated. Ohio EPA is continuing to work with the WWTP to address compliance issues.

L5.2.2.2 Second Report on Twin Creek 4B Demonstration (2014 Integrated Report)

A permit to install for WWTP improvements was approved on July 10, 2013. The approved upgrades include a fine spiral screen and continuously backwashed tertiary filters. The Village has been awarded Ohio Public Works Commission funding for completion of the project. The expected date of completion of construction is July 2014. The improvements are expected to reduce the solids being discharged from the treatment plant and therefore the associated organic enrichment, which is expected in turn to result in attainment of the designated aquatic life use.

L5.2.2.3 Third Report on Twin Creek 4B Demonstration (2016 Integrated Report)

The following upgrades have been completed and are on-line:

- A new fine spiral screen;
- Upgrade of the existing circular aeration tanks to a zoned system to support biological nutrient removal (BNR) processes;
- All new mechanical equipment installed in the existing clarifiers;
- Addition of tertiary moving bed sand filters;
- Ultraviolet (UV) disinfection upgrade;
- New generator;
- Sludge pumping upgrades for both the return activated sludge (RAS) and waste activated sludge (WAS); and
- Sludge storage improvements.

Operators are trying to optimize the WWTP operations with small changes such as fine bubble diffusers in the sludge holding tank. There have been challenges trying to meet the 1 mg/L total phosphorus

limit. Ohio EPA's Compliance Assistance Unit (CAU) has assisted with the operations at the plant. Other TMDL requirements were incorporated into the facility's NPDES permit when the permit was modified in April 2015.

L5.2.3 Sycamore Creek (Walnut Creek Watershed)

Problem causing the impairment.

Ohio EPA measured the water quality in the Walnut Creek watershed in 2005, collecting biological, chemical and physical data. Impairment of biological water quality standards (OAC 3745-1-07) was measured at six sites on Sycamore Creek, a tributary to Walnut Creek.

Three sites in Sycamore Creek met the biological criteria and three did not. The most upstream site (river mile (RM) 12.2) was impaired due to organic enrichment (probably due to septic systems), and then two sites (RMs 9.6 and 4.7) met the criteria. The next two sites (RM 4.18 (Hill Road) and 2.6 (Busey Road) partially met the criteria. The stream recovered to fully meet the criteria at the most downstream site (RM 0.2).

The City of Pickerington WWTP discharges to Sycamore Creek at RM 4.35. No impairment to Sycamore Creek immediately upstream of Pickerington or downstream of RM 2.6 was measured. The biological impairment is resulting from the Pickerington WWTP effluent discharge.

The site at RM 4.18 only partially met the WWH biological criteria. The fish community was in very good condition while qualitative invertebrate sampling revealed a low-fair community. This is likely caused by the proximity of the Pickerington WWTP to this sampling station and documented chronic toxicity of effluent to *Ceriodaphnia* (Ohio EPA, 2006, Bioassay Report 06-3447-C). Both fish and invertebrate communities improved at Sycamore Creek sites downstream of RM 4.18.

The chemical water quality criterion for total dissolved solids (1500 mg/L) was exceeded in Sycamore Creek downstream of the Pickerington WWTP (2110, 1950, 1710 mg/L).

Link between the source of the problem and the specific listed impairments

High total dissolved solids (TDS) concentrations result from the Pickerington WWTP discharge. The WWTP accepts a waste stream from the Pickerington water treatment facility which uses a Zeolite process to treat drinking water. This process creates a wastewater high in dissolved solids which the WWTP does not effectively treat. This high dissolved solids waste gets passed through the WWTP and into Sycamore Creek.

Bioassay testing results on the Pickerington effluent and mixing zone have confirmed TDS-related impairment to the invertebrate community as well by demonstrating negative effects (immotility, death) to *Ceriodaphnia*. Mayfly populations found downstream of the WWTP are impaired revealing only 2 mayfly taxa (compared with 8 found upstream of the discharge point) plus a variety of TDS tolerant and facultative invertebrates as well. The two sites upstream and the site at the mouth were in full attainment of WWH biological standards with moderately good (qualitative assessments at RM 9.6 and 4.7) to exceptional (ICI=50 at RM 0.2) communities of invertebrates.

Low fish MIWB scores found at RM 2.6 provide further evidence of a problem with excessive TDS in-

stream contributing to reduced numbers of fish.

Further information regarding the 2005 findings is available in the Biological and Water Quality Study of Walnut Creek and Select Tributaries 2005, available on Ohio EPA web site (http://www.epa.ohio.gov/portals/35/documents/WalnutCreek2005TSD.pdf).

Ohio EPA included total dissolved solids for this assessment unit in the 2008 Integrated Report (303(d) list), available at (http://www.epa.ohio.gov/dsw/tmdl/2008IntReport/2008OhioIntegratedReport.aspx).

Description of pollution controls and how they will achieve water quality standards

The City of Pickerington operates a sewer collection system and a wastewater treatment facility and is regulated under a NPDES permit (4PB00017*LD).

The existing Pickerington wastewater plant has an average daily design flow of 1.6 MGD. Pickerington is expanding its wastewater plant to an average design flow of 3.2 MGD to accommodate new development within its service area. Along with other improvements, for solids handling the City will construct two new aerobic digesters and new sludge drying beds for storage.

The permit requires the development of a method to control discharges of elevated dissolved solids. Both interim and final effluent concentrations of dissolved solids are present in the permit (calculated by wasteload allocation) which should serve to ameliorate the violations of the WQS in Sycamore Creek (see the NPDES permit fact sheet for the Pickerington WWTP: http://wwwapp.epa.ohio.gov/dsw/permits/permit_list.php).

Point and nonpoint source loadings that will achieve water quality standards.

The allowable loading is based on the beneficial uses assigned to the receiving waterbody in OAC 3745-1. Dischargers are allocated pollutant loadings/concentrations based on the Ohio Water Quality Standards (OAC 3745-1). TDS was allocated using the mass-balance method, using the following general equation:

Discharger WLA = [(downstream flow x WQS) - (upstream flow x background concentration)] / discharge flow.

See the permit fact sheet (http://www.app.epa.ohio.gov/dsw/permits/permit_list.php) for details.

The continuous discharge from the WWTP into Sycamore Creek at low stream flows during the summer represent the critical condition for the aquatic ecosystem. The WLA calculation accounts for the nonpoint source load in the equation. See the permit fact sheet (http://wwwapp.epa.ohio.gov/dsw/permits/permit_list.php) for details.

All loads in kg/d	Existing WWTP Flow	Expanded WWTP Flow
TMDL	11,022	20,433
LA	666	666
WLA	10,356	19,767

An estimate or projection of the time when WQS will be met

The NPDES permit requires the City of Pickerington to meet the final effluent limitations in the permit within 25 months of the effective date of the permit (in 2010). WQS should be met soon after as macroinvertebrates can recover quickly (6 months to a year) once the stressor is removed.

Schedule for implementing pollution controls

Reference the NPDES permit fact sheet for scheduling information (http://wwwapp.epa.ohio.gov/dsw/permits/permit_list.php).

Monitoring plan to track effectiveness of pollution controls

The City of Pickerington WWTP is required to submit monthly Discharge Monitoring Reports for effluent quality from the WWTP and upstream and downstream of its discharge point.

The permit requires 24-hour composite sampling for TDS of the WWTP effluent, to be completed three times per week year-round. In addition, the WWTP will collect an ambient grab sample for TDS at sites both upstream and downstream of the discharge into Sycamore Creek; they will use a laboratory of their choice.

The facility's monthly discharge monitoring reports are reviewed by permit staff in Ohio EPA's Central District Office. Ohio EPA staff will also conduct unannounced facility inspections until all identified operational and process changes have been completed.

Water chemistry and macroinvertebrate community health will be monitored following the construction and new plant start up. After the Pickerington WWTP improvements have been in place for at least one year, Ohio EPA will return to monitor Sycamore Creek to determine if progress toward meeting the Aquatic Life Use is being made. This work would follow Ohio EPA's protocol for sampling the aquatic biology and chemistry. If sufficient progress is not being made, Ohio EPA will evaluate the options available under NPDES authority, including operations assistance and enforcement.

Ohio EPA will report progress in its Integrated Report until the impairment has been eliminated.

Future monitoring

City of Pickerington (far field monitoring for TDS in the NPDES permit, analysis by a laboratory of their choice) and Ohio EPA DSW, CDO WQ (chemistry, with analysis by Ohio EPA DES) and EAS (macroinvertebrates).

Cost estimates

Five work days for two people to sample chemistry, 1 work day for two people to do qualitative macroinvertebrate monitoring, and the associated standard lab costs for TDS samples.

Analysis of the results and annual reporting

Ohio EPA, CDO, DSW WQ staff will examine both data from Ohio EPA sampling and that generated by Pickerington. EAS macroinvertebrate staff will analyze their own data. Ohio EPA CDO staff will complete the reporting necessary for this 4B demonstration.

Revising the implementation strategy and corresponding pollution controls

The CDO surface water manager will initiate a reexamination of the implementation strategy if significant progress is not being made by the end of the next NPDES permit cycle for Pickerington.

L6.2.3.1 First Report on Sycamore Creek 4B Demonstration (2012 Integrated Report)

The City of Pickerington replaced their ion exchange water treatment plant with a reverse osmosis water treatment plant in order to address the NPDES TDS effluent limit violations at their WWTP. Very soon after the new plant began operating, Pickerington returned to compliance with the NPDES permit conditions implementing the water quality criterion for TDS. Ohio EPA expects this to eliminate any impairment in Sycamore Creek.

L6.2.3.2 Second Report on Sycamore Creek 4B Demonstration (2014 Integrated Report)

Sycamore Creek has not been reevaluated for aquatic life use support since the 2012 Integrated Report. However, the facility has not reported any TDS violations since the reverse osmosis system was put in place (see figure below).

L5.2.3.3 Third Report on Sycamore Creek 4B Demonstration (2016 Integrated Report)

Sycamore Creek has not been reevaluated for aquatic life use support since the 2012 Integrated Report. However, the facility has not reported any TDS violations since the reverse osmosis (RO) system was put in place (see figure below). Pickerington's permit limit for TDS is 1,628 mg/L. On November 24, 2014, an exceedance of the permit limit for TDS was detected; however, the limit is based on a monthly average, which for November was approximately 1022 mg/L, well below the established limit. Therefore, compliance with the permit was maintained.

L5.3 Projects included in the 2014 Integrated Report

After completion of the 2012 Integrated Report and before completion of the 2016 Integrated Report, Ohio submitted one 4B alternative as part of an approved TMDL: Great Miami River (upper) watershed TMDL Report. Together with TMDLs approved for other impairments to the aquatic life use, the 4B work should bring the river into attainment with water quality standards.

L5.3.1 Great Miami River (Great Miami River (upper) Watershed)

During the 2008 field survey, Ohio EPA identified that the Great Miami River at river mile 158.15 was partially supporting its warmwater habitat aquatic life use. Identified causes of impairment included habitat alteration, siltation, flow alteration, and organic enrichment/dissolved oxygen (DO). Ohio EPA proposes that the organic enrichment/DO cause of impairment be handled through a category 4B alternative instead of a total maximum daily load (TMDL). Further details are discussed below.

Additional information is available in the main text of the TMDL report and in the biological and water quality study publication (http://www.epa.ohio.gov/portals/35/documents/Upper_GMR_TSD_2008.pdf).

Identification of segment and statement of problem causing the impairment

The Great Miami River upstream of the WWTP is in partial attainment of its aquatic life use because of habitat alteration, siltation, flow alteration, and organic enrichment/DO. Organic enrichment/DO is partially attributed to an upstream WWTP at RM 158.15 – Indian Lake/Logan County (OH0036641). Other sources include Indian Lake overflow of warm water in summer months and sediment from Cherokee Mans Run. Downstream of the WWTP, the river is sluggish from the effects of the low head dam impoundment in Quincy. This sluggish water is not allowing effective re-aeration of river water, which exacerbates the dissolved oxygen (DO) stresses caused by nutrient enrichment and sewage solids from the Logan County Indian Lake WWTP. The result is partial attainment downstream at Notestine Road (RM 153.45). Proper treatment of wastewater will help to alleviate the impacts to this stressed section of the Great Miami River.

The Logan County Indian Lake Sanitary Sewer District has an Infiltration and Inflow (I&I) problem in the collection system. Hydraulic surges during storm events overwhelm the collection and treatment systems causing a secondary treatment bypass. The result is the discharge of undertreated sewage with ammonia and solids entering the Great Miami River at RM 158.15, contributing to partial attainment due to low macroinvertebrate performance at Notestine Road (RM 153.45).

Description of pollution controls and how they will achieve water quality standards

On March 6, 2009 the Logan County Board of Commissioners was issued a NPDES permit number 1PK00002*KD for the discharge of treated waste water to the Great Miami River. This permit includes a compliance schedule for the elimination of a secondary treatment system bypass. This bypass allows for the discharge of primary treated waste water to go directly to the Great Miami River. The bypass contributes to additional organic and nutrient loadings to the river. The permit compliance schedule address both phase 1 and phase 2 projects designed to eliminate secondary treatment system bypasses at the plant. The phase 1 projects also will address several collection system overflows. The schedule requires completion of phase 1 projects by no later than July 1, 2011. The phase 2 projects are scheduled for completion by no later than July 1, 2016. On June 26, 2007 Permit to Install (PTI) 597728 was issued to the Logan County Water Pollution Control District. This PTI includes the following upgrades: a new 24" force main and lift station in the slough area; new influent fine screens; a new equalization tank (1.55 million gallons); conversion of existing primary clarifiers to equalization (0.5 million gallons); a new UV disinfection system; conversion of the anaerobic digesters to aerobic digester; and the addition of a new belt press and septage receiving station. The majority of the phase 1 projects were competed in early 2010. With the completion of this work the number of bypasses and collection system overflows has been reduced significantly. This will result in a reduction of loadings to the Great Miami River. With the completion of the phase 2 upgrades, all discharges from the plant will need to meet the water quality standards. This should eliminate any water quality impacts downstream resulting from treatment plant discharges.

Aquatic life use was assessed during the summer of 2008 while the WWTP facility was undergoing construction improvements (entitled Phase I). To address one of the causes of impairment, discharge monitoring report (DMR) data and a violations history from this facility were explored for any recognizable changes in performance before and after completion of Phase I. Other causes and sources of impairment (i.e., siltation, habitat alteration) are addressed in the TMDL project report under loading

development.

Phase I construction was completed in late December 2009. The quantitative analysis contained herein contrasts the Indian Lake WWTP performance prior to (January 2005 to December 2009) and following (January 2010 to May 2011) completion of Phase I construction. To summarize, the comparison shows the following changes:

- 1) Reduction in nutrient concentrations for final outfall (station 001) based on review of total phosphorus, ammonia, and nitrite/nitrate effluent data;
- 2) Increase in influent (station 601) concentration of carbonaceous BOD (CBOD) and total suspended solids (TSS);
- 3) Decrease in TSS spikes from final outfall (station 001);
- 4) Reduction in number of bypass occurrences around secondary treatment (station 602); and
- 5) Reduction in number of limit violations (TSS, ammonia, and pH) for final outfall (station 001).

While the improvements in effluent quality and WWTP operations are clearly manifest in 2010, they are somewhat confounded in 2011 due to anomalous meteorological and hydrological conditions within February through May. The upper GMR basin received considerable rainfall and experienced correspondingly high stream flow during late winter to mid spring 2011. Figure E-1 shows a frequency distribution of flow magnitude by percent exceedance for the GMR at Sidney OH for a record of over 25 years of daily flow. This gage is located 28 miles (river miles) downstream of the WWTP outfall. Flows during this period were consistently in the high percentile of non-exceedance. Flow produced from these rain events were exceeded 15 percent or lower over time (or *not* exceeded 85 percent or higher over time). Hence, some of unexpected results (discussed below by topic) following completion of Phase I construction can be explained by these anomalous high flows experienced within the WWTP collection area.

Figure E-1. Flow duration curve for data collected at USGS automatic gauge 03261500 (Great Miami River at

Sidney OH) for the period October 1985 through June 2011. Flows during 2011 that occurred between February 16 and May 31 are highlighted in red. All values reported as average daily flow in cubic feet per second (cfs).

Nutrient Loading (Station 001)

When examining loadings for total phosphorus and ammonia from the final outfall, there is a progressive decline from 2005 to 2010 for both summer season (Figure E-2) and annual (Figure E-3) compilations. However, mean daily loadings increased in 2011 (annual compilation) for total phosphorus but not for ammonia (Figure E-3). For nitrite and nitrate effluent loadings, there was no consistent decline in magnitude; though for the 2009 and 2010 summer season, magnitudes were considerably lower than in the previous four years (2005-2008) (Figure E-2). This decline was also apparent for annual nitrite and nitrate loadings – 2009 to 2011 was noticeably lower than in the 2005-2008 period (Figure E-3).

Figure E-2. Mean loading (in kg/day) of total phosphorus, ammonia, and nitrite+nitrate by year for <u>summer season</u> (June to September) observations for Station 001 (final outfall) of Indian Lake WWTP. The overall seven-year summer season mean loading is also shown.

Figure E-3. Mean loading (in kg/day) of total phosphorus, ammonia, and nitrite+nitrate by year for <u>annual</u> (January to December) observations for Station 001 (final outfall) of Indian Lake WWTP. The overall seven-year annual mean loading is also shown.

Influent Concentration (Station 601)

Concentrations of 5-day carbonaceous BOD (CBOD5) and total suspended solids (TSS) were examined for the influent station (station 601) to Indian Lake WWTP. Figures E-4 (summer) and E-5 (annual) are included to show mean concentrations by year and overall for both CBOD5 and TSS. The overall (2005-2011) mean concentration is shown as a seven-year "normal". Concentrations of influent TSS increased markedly in 2009, and subsequently in 2010 and 2011, to reflect improved changes in septage receiving (from HSTS). A reconfigured influent screening system changed the location of influent monitoring to now measure 100 percent of incoming septage.

The increased concentration seen in 2010 (summer and annual) and 2011 (annual only) compared to the 2005-2008 period can further be explained by completion of Phase I improvements on the wastewater *collection system*. The resultant increase in concentration for both of these parameters suggests improved capture of waste from the collection system – there is less dilution flow from infiltration and inflow problems and reduced storm water overflow from a slough area into the wastewater stream. The increasing multi-year trend in influent concentration for both TSS and CBOD5 are further supported by Figures E-6 and E-7, respectively, which show a time series with a 60-day running average and a large gain in the spring of 2009.

Figure E-4. Mean concentration (in mg/L) of CBOD 5-day and TSS by year for <u>summer season</u> (June to September) observations for Station 601 (influent) of Indian Lake WWTP. The overall seven-year summer season mean concentration is also shown.

Figure E-5. Mean concentration (in mg/L) of CBOD 5-day and TSS by year for <u>annual</u> (January to December) observations for Station 601 (influent) of Indian Lake WWTP. The overall seven-year annual mean concentration is also shown.

Figure E-6. Time series of TSS from January 2005 to May 2011 for station 601 for Indian Lake WWTP. A 60-day running average was also computed and overlaid (solid red line) on the individual observations.

Figure E-7. Time series of CBOD5 from January 2005 to May 2011 for station 601 for Indian Lake WWTP. A 60- day running average was also computed and overlaid (solid red line) on the individual observations.

Total Suspended Solids – Peak Events (Station 001)

A peak event is a high loading event and is defined here as a daily TSS load that exceeds 500 kg/day. The TSS permit limit for station 001 for this facility is 522 kg/day (weekly or average criterion). There were 34 of these events between 2005 and 2009 (Figure E-8). Performance following Phase I completion showed no high loading events for all 2010, and for those that occurred in 2011 – 6 of 7 events occurred in early March 2011.

Figure E-8. Time series of daily total suspended solid loads (kg/day) for Indian Lake WWTP for station 001 for the period January 2005 to May 2011.

Bypass Occurrence (Station 602)

Indian Lake WWTP bypass information such as number of occurrences per year and total and average volume of flow per year was examined and showed a marked decrease once Phase I was completed (Table E-1). A bypass event avoids secondary wastewater treatment and poses potentially significant harm to the receiving water. However, once into 2011 the number of bypass occurrences increased to 11 but all 11 events occurred after 2/17/2011 when the GMR basin, and corresponding WWTP collection area, experienced high percentile flood flows (Figure E-1). DMR data was only available to 5/27/2011 which is still within this identified high flow period. The sharp increase in 2011 also reflects the treatment plant's elimination of several bypasses within the collection system. Thus all of the flow that enters the system now makes it completely to the plant. The new expanded equalization system at the WWTP, as part of Phase I construction, will help capture more material before it is bypassed at the plant.

Table E-1. Summary of bypass information for Indian Lake WWTP (station 602) for the period 8/1/2006 to 5/26/2011.

Year	Number of Occurrences	Total Volume (MG)	Avg Volume per Occurrence (MG)
2006	9	22.4	2.49
2007	20	72.8	3.64
2008	22	84.8	3.85
2009	22	29.7	1.35
2010	6	12.1	2.02
2011 (5 months)	11	179.6	16.3

Limit Violations (Station 001)

A review of violations of permit limits for Indian Lake WWTP was made and is summarized in Table E-2 below. Both concentration and loading limit violations were considered and for both average (monthly) and maximum (weekly) statistical periods. While found in the review, violations for total chlorine residual were omitted because of insignificance to the impairment cause (DO/organic enrichment). Since completion of Phase I, there was a considerable reduction in number of violations (Table E-2). The four TSS violation events that occurred after Phase I completion all occurred in early March 2011.

Table E-2. Summary of limit violations for Indian Lake WWTP (station 001) for the period January 2005 to May 2011. Violations for total chlorine residual are omitted.

	Number of Limit Violations				
Parameter (code)	2005 - 2009	2010 - May 2011			
TSS (00530)	8	4			
pH (61942)	1	0			
ammonia (00610)	7	0			

Conclusion

The partial impairment of aquatic-life use that exists at RM 153.45 (Notestine Rd) of the GMR (12-digit HUC 05080001-03-02) is caused by multiple stressors and sources. While the predominant stresses are habitat alteration and siltation – a low gradient river system choked by sediment, a secondary stress is organic enrichment and low DO produced by an upstream POTW. The Agency aquatic-life use assessment was conducted and completed in 2008 but the POTW was in the midst of constructing improvements to minimize their bypass (of secondary treatment) occurrence and volume. The first phase (Phase I) of construction was completed in late December 2009. The above analysis described effluent quality and behavior by comparing results prior to and following this completion date. Though WWTP performance was confounded by high flows in early 2011 (February through May), 2010 performance was considerably better than that observed in the prior four years (2005-2008). Phase II construction will begin soon and address treatment levels needed to meet permit and water quality standards. The goal is that completion of Phase I and Phase II construction will, with high likelihood, remove the stressor of impairment associated with organic enrichment and low dissolved oxygen.

An estimate or projection of the time when WQS will be met

The June 2011 NPDES permit Part I,C-Schedule of Compliance paragraph f, gives April 1, 2017 as the date the Indian Lake Water Pollution Control Facility wastewater works will attain final compliance. Reevaluation of biological water quality standards shall begin no earlier than the field season of 2018.

Schedule for implementing pollution controls

On July 13, 2011, the Logan County Board of Commissioners were issued NPDES number 1PK00002*LD. This permit contains a compliance schedule for completion of phase 2 projects that will address secondary treatment system bypassing at the plant. The permit schedule includes the following compliance dates:

- 1. Submit an approvable "No Feasible Alternatives Analysis by no later than October 1, 2012.
- 2. Submit a general plan for upgrades design to eliminate the secondary bypass by no later than April 1, 2013.

- 3. Submit a Permit to Install for treatment system upgrades by no later than April 1, 2014.
- 4. Complete treatment system upgrades by no later than July 1, 2016.
- 5. Attain final compliance with NPDES permit limits and conditions by no later than April 1, 2017.

With the completion of the phase 2 projects, the Logan County Water Pollution Control District Indian Lake plant should be in compliance with their NPDES permit conditions, thus eliminating any effluent- derived water quality impacts downstream.

Monitoring plan to track effectiveness of pollution controls

As part of their NPDES permit, Indian Lake Water Pollution Control Facility wastewater works measures and reports plant bypasses at station 602 on a monthly basis. In addition, outfall 001 will report TSS, cBOD $_5$, phosphorus, ammonia and nitrate/nitrite discharges to the Great Miami River on a monthly basis. Sampling is done three times a week for TSS, cBOD $_5$, and NH $_3$. Phosphorus and NO $_2$ /NO $_3$ will be sampled once a week. SSO discharges will be reported within 24 hours of the occurrence. The facility's monthly discharge monitoring reports are reviewed by permit staff in Ohio EPA's Southwest District Office. Inspection of the facility will be done every two years starting in 2012.

No earlier than the field season of 2018, Ohio EPA will sample the impaired section of Great Miami River (RM 153.45, Notestine Rd.) for chemistry, fish and macroinvertebrates. The chemistry will be sampled at one location and five sampling events will be completed. The fish will be sampled at one location with two passes each. The macroinvertebrates will be evaluated on one sampling event. This work will follow Ohio EPA's protocol for sampling the aquatic biology and chemistry. The sampling will take place during the summer/fall sampling season with analysis by Ohio EPA's laboratory and reporting to Southwest District Office.

Commitment to revise pollution controls, as necessary

The SWDO surface water manager will initiate a reexamination of the implementation strategy if significant progress is not being made by the end of the next NPDES permit cycle for Indian Lake.

Ohio EPA will report on the progress of any approved 4B in future 303(d) lists.

L5.3.1.1 First Report on Great Miami River 4B Demonstration (2014 Integrated Report)

The facility completed a Phase One study / upgrade (\$ 10,000,000) in 2011. Phase One projects included new influent screens, two MGD in equalization, a new express force main and lift station, and upgrades to the solids handling systems (belt press and septage receiving). The sewer district reported seven SSOs and several secondary bypasses in 2013.

In addition, the sewer district has hired two consultants to work on aspects of the project. The district has begun a Capacity Management Operations and Maintenance program to oversee the collection system. New sewer use regulations have been implemented. In 2012 the district installed rain gauges and 18 flow meters. A model of the sewer is being developed. As part of the phase 2 work, the district is looking at treatment plant alternatives, maximizing existing treatment systems, and high rate treatment. The district is on schedule to meet the next deadline.

L5.3.1.2 Second Report on Great Miami River 4B Demonstration (2016 Integrated Report)

The Indian Lake Water Pollution Control District operates a 4.6 MGD WWTP that discharges directly to the Great Miami River. The plant serves the surrounding lake community as well as the communities of Lakeview, Russells Point, Belle Center and Huntsville. Excessive infiltration and inflow into the collection system has contributed to collection system bypasses and blending at the plant (blended flows are screened and disinfected before recombining with the final effluent).

In response the district performed a No Feasible Alternatives Analysis (2006) of both the collection and treatment systems. An adaptive management approach was selected. A two phase schedule was developed. Phase I work was completed in 2010. This phase included upgrades to the influent pump station; construction of new equalization basins (1.5 million gallons); installation of UV disinfection; updates to the bio solids dewatering equipment; and construction of a new pump station and force main was added to the Slough area.

As part of the Phase II work, the district is working on expansion of peak secondary and disinfection treatment capacities (peak 6.0 MGD plus). A PTI application for UV system upgrades was submitted in September, 2014. The district is upgrading the final clarifier weirs, baffles and mechanisms to allow for treatment of peak flows. With the completion of this work the amount of flow that receives complete secondary treatment will be significantly increased.

The schedule for implementation of the No Feasible Alternatives Analysis Phase II projects has been inserted in the district's NPDES permit. As part of an adaptive approach the district is evaluating the effectiveness of infiltration removal verses additional treatment. The district believes if infiltration and inflow into the system can be reduced by 30 percent, elimination of all wet weather overflows and bypasses will occur. The NPDES permit schedule includes the following dates:

- Study (model) and complete enough infiltration and inflow projects to get to a 10 percent infiltration and inflow reduction. (September 1, 2021)
- Study (model) and complete enough infiltration and inflow projects to get to a 20 percent infiltration and inflow reduction. (September 1, 2027)
- Study (model) and complete enough infiltration and inflow projects to get to a 30 percent infiltration and inflow reduction. (September 1, 2032)

With the completion of the various projects the impacts to the receiving stream should be diminished. Through the adaptive approach the district will be able to evaluate and prioritize projects that will provide the biggest improvements in the shortest time.

M

An Overview of Ground Water Quality in Ohio

Case: 3:17-cv-01514-JGC Doc #: 1-12 Filed: 07/18/17 529 of 601. PageID #: 1526

M1. Introduction

Section M summarizes water quality assessment data for Ohio's major aquifers based on information requested in the 2006 Integrated Reports Guidance and the 1997 Guidelines for Preparation of the Comprehensive State Water Quality Assessments.

Ground water protection programs for Ohio are briefly summarized in Section M2 as required by section 106(e) of the Clean Water Act. Programs to monitor, evaluate and protect ground water resources are implemented by various state, federal and local agencies. Ohio EPA is the designated agency for monitoring and evaluating ground water quality and assessing ground water contamination problems. Within Ohio EPA, the Division of Drinking and Ground Waters (DDAGW) carries out these functions and coordinates various ground water monitoring efforts within the agency and with other state programs. Short program descriptions are provided with links to program-based web pages to provide the most current information.

Ohio's three major aquifer types are described briefly in Section M3. More detailed descriptions of the major aquifers and water quality of the aquifers are provided in Appendix A. Where possible, the water quality data are associated with major aquifer types. The aquifer descriptions allow the reader to associate water quality with geologic settings.

Sections M4 and M5 summarize sites with verified ground water contamination and identify the major nonpoint sources of ground water contamination in Ohio. These data were obtained from various sources including:

- Potential contaminant sources inventoried as part of Ohio EPA DDAGW's Source Water Assessment and Protection (SWAP) program;
- Ground Water Impacts Database (maintained by Ohio EPA DDAGW);
- Underground injection control sites identified in Ohio EPA DDAGW and Ohio Department of Natural Resources (ODNR) – Division of Oil and Gas Resource Management databases;
- Leaking and formerly leaking underground storage tanks from Ohio Department of Commerce Division of Fire Marshal's Bureau of Underground Storage Tank Regulations (BUSTR) databases; and
- Federal databases listing Department of Development/Department of Energy (DOD/DOE) facilities and National Priorities List/Comprehensive Environmental Response, Compensation and Liability Act (NPL/CERCLA) sites.

In many instances, these data are not associated with the geologic setting of the impacted aquifer, so statewide summaries are provided.

Section M6 summarizes ground water quality impairments by parameter within Ohio's major aquifers. Two primary data sets are used in this analysis: the drinking water compliance data for public water systems (PWSs); and the Ambient Ground Water Quality Monitoring Program (AGWQMP) data. The PWS compliance data represents treated (post-processing) water distributed to the public. AGWQMP is an Ohio

EPA - DDAGW program created to monitor "raw" (untreated) ground water. The goal is to collect, maintain and analyze raw ground water quality data to measure long-term changes in the water quality of major aquifer systems. Since Ohio does not have statewide ground water quality standards, comparisons to primary maximum contaminant levels (MCL) or secondary maximum contaminant levels (SMCL) for drinking water were used.

Section M7 briefly discusses ground water-surface water interaction (GW-SW) and a few special studies that provide insight on the interaction, which lead to suggestions for future ground water monitoring efforts. Section M8 presents conclusions and recommendations for future direction concerning statewide ground water monitoring and protection of Ohio's major aquifers.

M2. Ohio's Ground Water Programs

State Coordinating Committee on Ground Water - The State Coordinating Committee on Ground Water (SCCGW) was created in 1992 by the directors of the state agencies that have ground water program responsibilities. The purpose is to promote and guide the implementation of coordinated, comprehensive and effective ground water protection and management programs for Ohio. The SCCGW is composed of ground water technical or management staff from seven state agencies, two federal agencies and The Ohio State University Extension office. Information about the SCCGW bi-monthly meetings and meeting summaries are available on the SCCGW Web site:

http://epa.ohio.gov/ddagw/SCCGW.aspx

Ohio Ground Water Protection Programs - Programs to monitor, evaluate and protect ground water resources in Ohio are administered by federal, state and local agencies. Ohio EPA is the designated state ground water quality management agency. The ODNR - Division of Water Resources is responsible for evaluation of the quantity of ground water resources. Ground water-related activities at the state level are also conducted by the Ohio Departments of Agriculture, Commerce (Division of State Fire Marshal), Health and Transportation. The United States Geological Survey (USGS), Ohio Water Science Center, contributes to these efforts with water resource research. Table M-1 (based on Table 5-2, U.S. EPA 305(b) Guidelines, 1997) summarizes agencies responsible for administering the various ground water programs in Ohio.

Table M-1. Summary of Ohio's ground water protection programs.

Programs or Activities	State Activity	Implementation Status*	Responsible Agency
Active SARA Title III Program	✓	E	Ohio EPA – DERR or DMWM?
Ambient ground water monitoring system	✓	E	Ohio EPA – DDAGW
Aquifer vulnerability assessment	√	CE	ODNR – DWR Ohio EPA – DDAGW

M3. Ohio's Major Aquifers

Introduction

Ohio has abundant surface and ground water resources. Average rainfall ranges between 30 and 44 inches/year (increasing from northwest to southeast), which drives healthy stream flows. Infiltration of a small portion of this rainfall (3-16 inches) recharges the aquifers and keeps the streams flowing between rains. Ohio's aquifers can be divided into three major types as illustrated in Figure M-1. The sand and gravel buried valley aquifers (in blue) are distributed through the state. The valleys filled by these sands and gravels are cut into sandstone and shale in the eastern half of the state (in tans) and into carbonate aquifers (in greens) in the western half. The buried valley aquifers are productive aquifers. The sandstone and carbonate aquifers generally provide sufficient production for water wells except where dominated by shale, as in southwest and southeast Ohio. An Ohio EPA report, *Major Aquifers in Ohio and Associated Water Quality* (2015), provides more detailed descriptions of these aquifers. This report is included here as Appendix A.

Characterizing Aquifers

In a continuing effort to characterize ground water quality for the professional/technical community and the general public, DDAGW is writing technical reports and fact sheets on the distribution of specific parameters in Ohio. The goal of these reports is to provide water quality information from the major aquifers, exhibit areas with elevated concentrations and identify geologic and geochemical controls. This information is useful for assessing local ground water quality, water resource planning and evaluating areas where specific water treatment may be necessary. A series of parallel fact sheets targeted for the general public provide basic information on the distribution of the selected parameters in ground water. The information in the fact sheets is presented in a less technical format, addresses health effects, outlines treatment options and provides links to additional information.

Figure M-1. Aquifer types in Ohio modified from ODNR glacial and bedrock aquifer maps (ODNR, 2000; http://water.ohiodnr.gov/maps/statewide-aquifer-maps)

Since the Ohio 2014 Integrated Report, technical reports and fact sheets on reduction-oxidation (redox) control of water quality and distribution of strontium have been completed. The Major Aquifers in Ohio and Associated Water Quality report, included as Appendix A, was also completed and then updated in October 2015. The redox report is not structured around a constituent or group of constituents like the other technical reports. However, Reduction - Oxidation (Redox) Control in Ohio's Ground Water Quality was completed to help ground water users understand the influence redox processes have on water quality. The redox condition of water is a conceptual framework for understanding the behavior of some common water quality parameters. For example, the iron staining of plumbing fixtures, ground water with a rotten egg smell and the presence of arsenic all relate to the redox state of the water. All bodies of water, from aquifers to streams to glasses of water, have redox states that are mediated by microbes and electron transfer reactions. The technical report focuses on a general understanding of redox as it relates to ground water quality, using Ohio raw water data to illustrate these relationships. Figure M-2 illustrates the depth related redox pair reactions (on right) with their redox zones (on left). Generally, ground waters are more reduced with increased depth below the water table. The report also includes several examples that show how redox concepts can be applied to understand the behavior and persistence of some common ground water contaminants, both natural and anthropogenic.

Figure M-2. Sequence of redox sensitive parameter changes with depth.

Strontium Distribution and Source

Based on the initial occurrence data on strontium collected for the Unregulated Contaminant Monitoring Rule 3 (UCMR3), the U.S. EPA made a preliminary determination in October 2014 to develop a drinking water standard for strontium. The U.S. EPA is continuing to evaluate information about strontium prior to making a final determination, but a final decision is not expected in 2016. Strontium concentrations in raw water in portions of Ohio carbonate aquifers are above health advisory levels. A draft technical report, *Strontium in Ohio's Ground Water* was generated to identify the areas in Ohio with elevated strontium and to identify the geologic and geochemical controls for the distribution.

In Ohio, the Silurian and Devonian carbonate aquifers in the western half of the state exhibit regional areas with strontium well averages up to $40,000~\mu g/L$ in raw water based on AGWQMP data. The sandstone aquifers exhibit the lowest strontium concentrations and the sand and gravel aquifers are intermediate. Strontium exceeds the life-time health advisory level $(4,000~\mu g/L)$ in raw water in over 85 percent of the carbonate wells and 15 percent of the sand and gravel wells in the AGWQMP. The current distribution of the carbonate aquifers is controlled by the Findlay Arch and glacial erosion. The highest levels of strontium in ground water (>25,000 $\mu g/L$) occur within a north-south belt along and to the east of the crest of the Findlay Arch as illustrated in Figure M-3.

Strontium replaced calcium and/or magnesium during the depositional processes of marine carbonates and evaporite minerals. The Late Paleozoic secondary mineralization remobilized and/or added additional strontium and concentrated celestine along fractures and other open structures in carbonate aquifers. Natural dissolution of limestone, dolomite and gypsum are certainly contributing strontium to the groundwater, but the highest concentrations of strontium are not associated with the highest concentrations of calcium, magnesium and sulfate. Thus, it appears celestine also contributes strontium to ground water. Two factors likely to control the dissolution of celestine (SrSO₄) are the presence of gypsum and redox conditions. Gypsum is more soluble than celestine, so dissolution of gypsum should reduce the dissolution of celestine by raising the sulfate concentration. However, when reducing conditions cause the reductive dissociation of sulfate, the lowered sulfate concentrations increase the dissolution of sulfate

minerals, including celestine. The highest strontium concentrations are associated with stratigraphic units with little gypsum, indicating celestine is a significant contributor to the higher strontium concentrations.

Figure M-3. Strontium distribution in Ohio.

M4. Site-Specific Ground Water Contamination Summary

Table M-2 (based on Table 5-3, U.S. EPA 305(b) Guidelines, 1997) provides a summary of the sites that have verified ground water contamination in Ohio. These data come from various state programs and the quality of these data is variable. Because the specific hydrogeologic settings for many of these sites is not included in the databases or is unknown, only a statewide summary is provided. Additional information is provided below for each program or subset of sites listed in Table M-2.

Table M-2. Ground Water Contamination Summary.

Hydrogeologic Setting: Statewide

Data Reporting Period: As of November, 2015

Source Type	Number of sites	Number of sites that are listed and/or have confirmed releases	Number of sites with confirmed ground water contamination	Contaminants
NPL - U.S. EPA	37 6 proposed	37	25	Mostly VOCs and heavy metals; also, SVOCs, PCBs, PAHs and others
CERCLIS (non- NPL) - U.S. EPA	419	419	20	Varied
DOD/DOE	128ª	71	68	Varied
LUST	35,147 ^b	1,904	165°	BTEX
RCRA Corrective Action	160	160	160	VOCs, heavy metals, PCBs and others
Underground Injection	Class ^d : I - 10 II - 411 III - 48 IV - 5 V - 49,727	0 0 0 0 0 14,238	0 0 0 0 NA	
State Sites ^e	772	772	254 ^f	Varied GW Impacts
Nonpoint Sources	NA	NA	NA	

Notes: NA - Numbers not available

^a Includes DOE, DOD, FUSRAP and FUD sites

b Includes only active LUST sites - Source: Ohio's State Fire Marshal, Bureau of Underground Storage Tank Regulations

^c Sites in Tier 2 or Tier 3 cleanup stages. Source: Ohio's State Fire Marshal, Bureau of Underground Storage Tank Regulations

^d Class I and V injection wells are regulated by Ohio EPA. Class II and Class III injection wells regulated by the Ohio Department of Natural Resources, Division of Oil and Gas Resources. Class IV injection wells are illegal in Ohio, except where approved as part of remediation plan.

^e Facilities in Ohio EPA's Ground Water Impacts database

^f A site is considered to be contaminating ground water if the "Uppermost Aquifer" or "Lower Aquifer" is noted to be impacted, as documented in Ohio EPA's Ground Water Impacts database.

Federal National Priorities List (NPL): Currently, 37 sites in Ohio are on the NPL, most of which (25) have been found to be affecting ground water quality. The primary contaminants are volatile organic chemicals (VOCs) and heavy metals.

CERCLIS (non-NPL): Ohio has 419 sites in the federal CERCLIS database.

DOD/DOE: The 128 sites on this list are the Department of Defense (DOD)/Department of Energy (DOE) sites in Ohio, including those that are Formerly Used Defense Sites (FUDS) and Formerly Utilized Sites Remedial Action Program (FUSRAP) sites. Of these, 68 have had confirmed releases to ground water.

Leaking Underground Storage Tanks (LUST): In Ohio, underground storage tanks (USTs) are under the jurisdiction of the State Fire Marshal, Bureau of Underground Storage Tank Regulation (BUSTR). Current data indicates that more than 35,000 sites have been found to be leaking. Of these, 1,904 have confirmed releases, with 165 having a release to ground water. The primary contaminants are the petroleum products of benzene, toluene, ethyl benzene and xylenes (BTEX).

RCRA Corrective Action: Currently, 160 facilities are in RCRA corrective action. All of these have confirmed releases to ground water. The primary contaminants are VOCs and heavy metals. This information was obtained from the RCRA Facility Database, an internal DDAGW tracking system.

Underground Injection: There are five classes of underground injection wells:

- 1) Class I wells inject hazardous wastes or other wastewaters beneath the lowermost aquifer;
- 2) Class II wells inject brines and other fluids associated with oil and gas production beneath the lowermost aquifer;
- 3) Class III wells inject fluids associated with solution mining of minerals beneath the lowermost aquifer;
- 4) Class IV wells inject hazardous or radioactive wastes into or above aquifers (these wells are banned unless authorized under a federal or state ground water remediation project;
- 5) Class V wells comprise all of the injection wells not included in Classes I-IV.

The Ohio Department of Natural Resources, Division of Oil and Gas Resources regulates Class II (411) and Class III (48) wells. The number of Class II brine injection wells (one of three types of class II wells) is increasing because of their use in disposal of fluids used in oil and gas drilling and shale gas development. In addition to the 210 active brine injection wells there are 17 wells that are drilled or being drilled and 18 that are permitted.

Ohio EPA DDAGW regulates Class I (10), Class IV (5) and Class V (+49,727) wells. Although owners and operators of Class V wells are required to register or permit their wells, there are still many that are unknown and unregistered throughout the state.

State Sites: State sites include landfills, RCRA-regulated hazardous waste facilities, unregulated sites (pre-RCRA) and sites investigated through the Voluntary Action Program (VAP). Ground water contamination summary information concerning many of these sites is tracked in the Ground Water Impacts Database, maintained by Ohio EPA - DDAGW. The database consists of sites with verified contaminant release to ground water. As of November 2015, the database contained 772 sites. Of the 772 sites, 254 have affected ground water quality within the uppermost aquifer or lower aquifer.

M5. Major Sources of Ground Water Contamination

Data show much of Ohio's ground water is of high quality and has not been widely influenced by anthropogenic activities, but individual cases of contamination are documented every year from point (site-specific locations) and nonpoint sources. Ohio has a diverse economy and the state uses and produces a range of potential contaminants applied, stored and disposed of in various land use practices. Consequently, ground water quality is susceptible to contamination from a range of substances and a variety of land use activities. Selecting major sources of contamination is subjective because the selection is scale-dependent. For an individual with contaminated water, the major source is the source that contaminates their well, regardless of the major sources identified for the state. From a statewide perspective, major sources are discussed below.

The ten major sources of ground water contamination in Ohio are indicated in Table M-3 (Table 5-1, U.S. EPA 305(b) Guidelines, 1997) by checks (✓). These data were obtained from two main sources: Ohio's Source Water Assessment and Protection (SWAP) Program and DDAGW's Ground Water Impacts Database. The SWAP Program has completed an inventory of the potential sources of ground water contamination in the delineated Drinking Water Source Protection Areas. This inventory is updated when the SWAP delineation is revised, for example, when new wells are approved. Ninety-nine percent of active public water systems that use ground water have had an inventory conducted, an analysis of the aquifer's susceptibility to contamination completed and a determination of whether the ground water quality has been impacted by anthropogenic activities. The Ground Water Impacts Database provides information regarding sites where contamination of ground water has been confirmed. These data were evaluated and those sources of highest concern were given a check mark (✓) in Table M-3.

Some of the "potentially high priority" sources, indicated by crosses (*), were selected based on professional knowledge of the types of sources that exist in Ohio. These sources, such as animal feedlots and mining, are limited in their extent, or are concentrated in regions of the state and may not be sited close to public water system well fields. Thus, they do not rank in the highest priority sources. However, where they are prevalent, these sources may be a threat to local ground water resources, especially in areas with sensitive hydrogeologic settings. Land use activities within sensitive areas have a greater potential of affecting ground water quality

Table M-3. Major sources of potential ground water contamination.

Contaminant Source	Highest- Priority Sources	Factors Considered in Selecting a Contaminant Source	Contaminants
Agriculture Activities			
Agricultural chemical facilities			
Animal feedlots	×	4, 5, 6, 8	E, J, K, L
Drainage wells			
Fertilizer applications (manure application)	✓	1, 2, 3, 4, 5, 8	E, J, K, L
Irrigation practices			
Pesticide applications			
On-farm agricultural mixing and loading			
Land application of manure			
Storage and Treatment Activities			
Land application			
Material stockpiles			
Storage tanks (above/below ground)	✓	1, 2, 3, 4, 5, 6, 7	C, D, H, M
Surface impoundments	×	6	G, H, M
Waste piles			
Waste tailings			
Disposal Activities			
Deep injection wells			
Landfills	✓	1, 2, 3, 4, 5, 6	A, B, C, D, H, M
Septic systems	✓	1, 2, 3, 4, 5, 6	E, H, J, K, L
Shallow injection wells	✓	1, 2, 3, 4, 5, 6, 8	C, D, G, H, M
Other			
Hazardous waste generators			
Hazardous waste sites	✓	1, 2, 3, 4, 5, 6, 7	A, B, C, D, H, I, M
Large industrial facilities			
Material transfer operations			
Mining and mine drainage	×	6, 8	G, H
Pipelines and sewer lines	✓		D, E, J, K, L
Salt storage and road salting	✓	6	G
Spills	×	6	C, D, H, M
Transportation of materials			
Urban runoff (storm water management, storm drains)	✓	2, 4	A, B, C, D, G, H, J
Small-scale manufacturing and repair shops	✓	4, 6	C, D, H, M

Notes: (✓) Highest Priority

(x) Potentially High Priority

Factor and Contaminant codes on next page.

FACTORS	CONTAMINANTS
Human health and/or environmental risk (toxicity)	A. Inorganic pesticides
2. Size of the population at risk	B. Organic pesticides
3. Location of the sources relative to drinking water sources	C. Halogenated solvents
4. Number and/or size of contaminant sources	D. Petroleum compounds
5. Hydrogeologic sensitivity	E. Nitrate
6. State findings, other findings	F. Fluoride
7. Documented from mandatory reporting	G. Salt/Salinity/brine
8. Geographic distribution/occurrence	H. Metals
	I. Radionuclides
	J. Bacteria
	K. Protozoa
	L. Viruses
	M. Other (VOCs)

Contaminant Source Discussion - All of the sources listed in Table M-3 are potential contaminant sources in Ohio and each may cause ground water quality impacts at a local scale. The sources identified as "highest priority" or "potentially high priority" are listed below in the order presented in Table M-3 and discussed briefly to provide additional information.

(✓) Highest Priority Sources

- Fertilizer Applications: Use and handling of fertilizers, manure and biosolids can cause ground water pollution. Human and animal biosolids used as fertilizer and chemical fertilizers contribute to nitrate contamination in ground water. Nitrate concentrations in ground water represent one of the better examples of the widespread distribution of nonpoint source pollution. Non-agricultural sources, such as lawn fertilization, sludge application and septic systems also contribute to localized nitrate ground water contamination. Public water systems utilizing sand and gravel aquifers have higher average nitrate levels than PWSs using sandstone and carbonate aquifers, primarily due to the higher vulnerability of unconsolidated aquifers and the shallower nature of the sand and gravel aquifers.
- Storage Tanks (Underground and Above-ground): There are 1,904 USTs known to be leaking or undergoing remediation in Ohio. Of these, 332 have been located in drinking water source protection areas for public water systems using ground water. Above-ground tanks are also prevalent throughout Ohio, with 1,284 located in a drinking water source protection area for public water systems using ground water. Many of these are smaller tanks used to store fuel oil for heating individual homes and many are old and rusty with no containment in the event of a leak or spill. Leaking above-ground storage tanks (ASTs) from commercial and industrial facilities are less of an issue, although catastrophic failure can create significant pollution problems to both ground water and surface water. There are only 21 ASTs in the Ground Water Impacts database known to be contaminating ground water from regulated hazardous waste facilities.
- Landfills: Currently, there are 128 landfills with documented ground water contamination in Ohio.
 This constitutes 50 percent of the sites known to be affecting ground water quality based on information in Ohio EPA's Ground Water Impacts database. Most likely, these are from older, unlined landfills (many of which are closed) or construction and demolition debris landfills (C&DD)

with limited construction standards. The current siting, design and construction standards for landfills are more stringent than twenty years ago, with the result that new landfills have significantly lower potential to impact ground water quality. Efforts to monitor C&DD landfills and characterize associated ground water quality impacts were reduced in 2015.

- Septic Systems: Over 1,000,000 household wastewater systems, primarily septic tanks and leach fields, or in some cases injection wells, are present throughout the rural and unsewered suburban areas of Ohio. A number of these systems are improperly located, poorly constructed, or inadequately maintained and may cause bacterial and chemical contamination of ground water which may supply water to nearby wells. Improperly operated and maintained septic systems are considered significant contributors to elevated nitrate levels in ground water in vulnerable geologic settings (e.g., shallow fractured bedrock and sand and gravel deposits). Over 2,000 septic systems are located in drinking water source protection areas. The updated Household Sewage Treatment Systems Rules became effective on January 1, 2015 (Ohio Revised Code Chapter 3718 and Ohio Administrative Code 3701-29) and should help correct deficiencies of failing septic systems.
- Shallow Injection Wells: Class V injection wells are widespread throughout the state. High concentrations of Class V injection wells are most likely found in areas with sensitive sand and gravel aquifers. It is estimated that Ohio has over 50,000 class V injection wells. The fact that these wells are used to inject fluids directly into vulnerable aquifers in the State is the main cause for concern. These shallow injection wells provide a direct pathway for nonpoint source contamination and illegal waste disposal into vulnerable aquifers. Ohio has closed 591 motor vehicle waste disposal wells (e.g., oil, radiator fluids, etc.) since 2000.
- Hazardous Waste Sites: Ohio generates a large amount of hazardous waste. Legacy hazardous
 waste sites are a serious threat to ground water. There are 63 RCRA hazardous waste facilities,
 15 Voluntary Action Program sites and 61 unregulated hazardous waste remediation sites (pre
 1980) with documented releases to ground water (uppermost or lower aquifer) based on the
 Ground Water Impacts Database.
- Pipelines and Sewer Lines: Pipelines and sewer lines all have potential for failure with release of the
 transported material. In addition, the construction of these lines, with the pipe embedded in
 permeable material, allows the trench to provide rapid flow paths for other surface contaminants.
 This is especially true if the trench is dug into fractured bedrock. Numerous gas, oil and industrial
 pipelines (1,215) and sewer lines (831) have been inventoried in drinking water source water
 protection areas.
- Salt Storage and Road Salting: The widespread use of salt or mixtures of salt and sand for deicing roads has been documented as a nonpoint source contributor of sodium and chloride contamination of shallow ground water (Jones and Sroka 1997; Mullaney et al. 2009). Spreading of salt on roads certainly contributes to ground water quality impacts, but the greatest local impact is associated with salt storage. In 2012-2014, Ohio EPA documented impacts to ground water at numerous salt storage facilities, including salt storage piles in drinking water source protection areas. Eighty-one (81) salt storage piles were identified in or near drinking water source protection areas with 62 of these located in sensitive aquifer settings. Most of these sites had adequate covering and pads. Ten sites were selected for additional investigation, two of which exhibited elevated chloride concentrations in ground water due to leaching of brine from the salt

pile. In addition to addressing these sites, Ohio is exploring ways to encourage implementation of BMPs for proper salt storage. Alternative chemicals like acetate-based deicers in combination with reduced salt usage are being promoted in pollution prevention programs. The workgroup, consisting of members from the Ohio Water Resources Council and the State Coordinating Committee on Ground Water, developed guidance for salt storage in 2013: *Recommendations for Salt Storage: Guidance for Protecting Ohio's Water Resources*, located on the web at: http://epa.ohio.gov/portals/35/owrc/SaltStorageGuidance.pdf

- Suburban Runoff (including storm drains and storm water management): With expanding suburban areas, nonpoint source contamination from suburban/urban runoff is an increasing source of ground water contamination, in contrast with most of the other sources discussed. In addition, the practice of constructing storm water retention basins increases the likelihood that storm water runoff infiltrates into ground water. More than 1,200 storm drains have been located in drinking water source protection areas, with many of these going directly to nearby water bodies. Elevated chloride is documented in urban areas within glacial aquifers by Mullaney et al. (2009) and positive trends in chloride concentrations in Ambient Ground Water Quality Monitoring data are present at some sites.
- Small-Scale Manufacturing and Repair Shops: Small-scale manufacturing and repair shops include 1693 facilities in drinking water source protection areas. These include: auto and boat repair shops and dealers, gas stations, junk yards, equipment rental and repair, machine shops, metal finishing and welding shops and other various small businesses. These businesses typically handle chlorinated solvents (for cleaning) and petroleum products. Limited knowledge of best management practices for handling and disposing of these products increases the risk of impacting ground water.

(x) Potentially High Priority Sources

- Concentrated Animal Feeding Operations (CAFO): The growth of CAFOs in numbers and size makes them a significant potential source if the waste is not properly managed. The ground water threats associated with CAFOs are captured in other categories as well, such as manure, sludge and fertilizer application and surface impoundments, so they are not considered one of the ten highest priority sources. Improper storage or management of the animal waste is the greatest threat to ground water contamination in sensitive hydrogeologic settings, but land application in solid or liquid form also poses risks for ground and surface water contamination.
- Surface Impoundments: Surface impoundments are one of the most common waste disposal concerns at RCRA facilities. Historically, they have been a major source for ground water contamination. Older impoundments were not subject to the same engineering standards as newer impoundments and, consequently, the probability of fluids leaching to the ground water was greater. Current siting and engineering requirements have improved this situation. Fifty-four (54) surface impoundments are known to be contaminating ground water based on information obtained from Ohio EPA's Ground Water Impacts database, the vast majority being from regulated and unregulated hazardous waste facilities.
- Mining and Mine Drainage: The bedrock (Pennsylvanian Units) that underlies eastern Ohio includes significant coal resources. The disruption of the stratigraphic units and oxidation of sulfides associated with coal mining produces ground water contamination by acid mine waters. Acid mine

waters are considered a significant threat to ground water in mined areas.

• Spills and Leaks: Leaks and spills of hazardous substances from underground tanks, surface impoundments, bulk storage facilities, transmission lines and accidents are major ground water pollution threats. More than a thousand leaks and spills are reported each year. This release of chemicals on to the surface and into near surface environments is certainly one of the greatest threats to ground water quality. The development of shale gas and associated hydrofracturing activity in eastern Ohio has raised concerns about potential for aquifer impacts. Historically, the surface management of brines has been the greatest cause of ground water contamination associated with oil production and hydro fracking activities (State Oil and Gas Agency Groundwater Investigations; and Their Role in Advancing Regulatory Reforms, GWPC, August 2011). Revised regulations address the management and disposal of oil and gas production brines with the preferred mode of disposal as injection into Class II injection wells.

The major sources of ground water contamination listed include point and nonpoint sources in roughly equal proportions. In strict terms, a point source is a discharge from a discernable, confined and discrete conveyance, but in practical terms, the distribution or spatial scale of a contaminant controls the designation of a source as point or nonpoint. For example, salt applied for de-icing along roads exhibits nonpoint source behavior, while salt stockpiles behave more like point sources, with the potential for continual release of concentrated brine that may affect ground water quality. This dichotomy is typical of many agricultural contaminants, manure spreading versus storage, fertilizer application versus storage or mixing sites. In Ohio, we generally have better documentation of ground water contamination associated with point source contamination than nonpoint source contamination due to the extensive ground water monitoring programs at regulated facilities.

Rapid runoff in glacial till areas overlying much of Ohio and drainage tiling have protected many of Ohio's aquifers from traditional nonpoint source pollution sources such as nitrate, chloride, pesticides or bacteria. In sensitive settings (e.g., sand and gravel aquifers, shallow bedrock aquifers), indicators of nonpoint source pollution are more clearly identified in Ohio's Ambient Ground Water Quality Monitoring Program and the public water system compliance monitoring data. However, these monitoring programs do not focus on shallow aquifers, which have a higher likelihood of being influenced by nonpoint source pollution such as agricultural practices.

M6. Summary of Ground Water Quality by Aquifer

Tables M-4A and M-4B (Table 5-4, U.S. EPA 305(b) Guidelines, 1997) summarize water quality compliance data from Ohio public water systems (PWSs) and raw water data from the AGWQMP, respectively. The compliance data for PWSs in Ohio (Table M-4A) documents water quality for treated water (post processing) and some raw (untreated) water quality (like new well samples). Parameters generally unaffected by standard treatment, such as nitrate, may be used to characterize Ohio's ground water quality because post treatment values are similar to ground water values. DDAGW created the AGWQMP program (Table M-4B) to monitor "raw" (untreated) ground water. This program's goal is the collection, maintenance and analysis of raw ground water quality data to measure long-term changes in the water quality of the Ohio's major aquifer systems.

Ohio does not have statewide ground water quality standards, so data for the major aquifers are compared

to primary maximum contaminant level (MCL) or secondary maximum contaminant level (SCML). Primary MCLs are the highest level of a contaminant that is allowed in public drinking water and are set as close to MCL Goals (a health-based standard) as feasible using the best available treatment technology and economic considerations. Primary MCLs are enforceable standards. Secondary MCLs are non-enforceable guidelines regulating contaminants that may cause cosmetic effects (such as skin or tooth discoloration) or aesthetic effects (such as taste, odor, or color) in drinking water.

Primary and secondary MCLs are used as practical benchmarks for water quality characterization in Tables M-4A and M-4B. Fifty percent of the MCL to 100 percent of the MCL is used as the range for the "watch list" determination. The PWSs or wells identified in this category may warrant additional monitoring to identify increasing trends. MCL exceedances are used as the criteria for the "impaired" category. Tables M-4A and M-4B were generated using the last 10 years of data (1/1/2005-12/31/2014). Mean concentrations of a parameter are used for deciding if a PWS or well is included in the watch list (50 percent to 100 percent MCL) or impaired category (> MCL). Maximum concentrations of nitrate and nitrite are reported in these tables instead of averages, due to the acute nature of their health concerns.

Public Water System Compliance Data

Mean values were calculated from PWS compliance data for 2005-2014 to determine the number of PWSs on the watch list and in the impaired category. A ten-year period of record was used to increase the statistical significance of the determination due to the infrequent sampling requirements (e.g., once per three-year period). PWSs included in the impaired category may not match Safe Drinking Water Act regulatory determinations of a violation due to the method of calculation. An MCL exceedance for compliance is generally an annual average, so the decadal average presented in Table M-4A is not a compliance number, but rather a comparison to MCL values, as a benchmark to identify PWSs in the watch list and impaired categories.

Table M-4A lists all parameters with MCLs (and SMCLs) and summarizes the number of PWSs in the watch list and impaired category for both raw and treated water quality data. The results for each parameter are further divided into major aquifer type categories. The total number of PWSs with data used in these determinations is presented to allow comparison of the total number of PWSs to those that exhibit elevated concentrations of MCL parameters. Data from active and inactive systems is included in Table M-4A. For parameters with SMCLs, treated water data is limited or absent because compliance data is generally not required for aesthetic water quality issues.

Final draft

Table M-4A. Counts of PWSs where 2005-2014 decadal mean values of compliance data occur in the Watch List and Impaired Category.

Note: presented by major aquifer types.

Blank spaces indicate no PWSs exceed the standards (zeros left out to highlight impacted PWSs); "nda" indicates no data available

- * Numbers for nitrate and nitrite are based on maximum values to reflect the acute nature of the contaminant.
- ** If Gross Beta result is less than 50 pCi/L no conversion to mrem/yr is necessary table used 50 pCi/L as standard.
- *** MCL is for combined Radium 226 and Radium 228

With the exception of a new well analysis, there are no requirements for collecting and reporting raw water data, so the number of PWSs with raw water data is less than the number with treated water data. The PWS data were linked to geologic settings using the DDAGW Source Water Assessment data, which allowed the breakout of the data by major aquifer. In this analysis, any detection in raw water data was used to generate PWS averages. For treated water data, PWS averages were generated only if there were at least two detections of a parameter. The inorganic parameters that place numerous PWSs in the watch list and impaired category warrant additional analysis.

The number of PWSs in the watch list and the impaired categories of Table M-4A are generally low; however, several parameters do exhibit higher numbers of PWSs in these groups. Fortunately, most of these occurrences are for secondary MCLs, not primary MCLs. That is, the water quality impacts documented are mostly aesthetic issues and are not health-based. Groups of parameters are discussed individually.

Inorganic Parameters MCL

Parameters

Only a few PWSs fall into the watch list or the impaired MCL category based on inorganic parameters. For treated water data, parameters with MCLs and <u>no PWSs</u> in the impaired category (values > MCL) include, **asbestos, barium, cadmium, chromium, cyanide, fluoride and selenium.** The use of detection limits at or greater than 50 % of the MCL and using the reporting limit for the non-detect value can result in PWSs placed in the watch list with no detection of the parameter. The data has been reviewed to assure that PWS in the watch list have detected the parameter. Factors limiting the number of PWSs in these categories include limited solubility of the substance in water, low crustal abundance, local geology and possibly treatment. For example, in treated water, no PWSs that exceed the fluoride MCL, but 27 PWSs that draw water from carbonate aquifers, exceed 50 percent of the MCL. This association is controlled by secondary fluorite mineralization along fractures and voids in limestone in northwest Ohio.

Several parameters including **antimony**, **beryllium**, **mercury and thallium** have low numbers of PWSs in the MCL impaired category for treated water. This small number is consistent with the low solubility and scarcity of these metals in Ohio's geology. The use of decadal averages for building both watch list and impaired categories may overestimate the numbers of PWSs when compared to actual MCL or SMCL calculations which use annual averages.

The number of PWSs with **arsenic** in raw water and treated water above the MCL (136 and 91, respectively) is consistent with the number of PWSs that DDAGW worked with to reduce arsenic to meet the 2006 revised MCL of 10 μ g/L. These systems are associated with reduced ground water and local areas of naturally occurring arsenic. Sand and gravel and carbonate aquifers are more likely than the sandstone aquifers to exhibit arsenic-impaired ground water. The number of PWSs currently exceeding the arsenic MCL is significantly less than what is listed in Table M4-A because numerous PWSs have installed treatment to remove arsenic since 2006. The elevated arsenic results collected from 2005 to 2006 and beyond (while treatment processes were installed and refined) are included in the ten years of data used to generate the PWS decadal averages. These elevated values increase the decadal mean calculated for Table M4-A and thus, result in impaired systems on a decadal mean, but these systems are currently serving water below the Arsenic MCL. Figure M-4 illustrates the distribution of the PWSs with arsenic in treated and/or raw water greater than the MCL as listed in Table M-4A.

Figure M-4. Distribution of PWSs on impaired list for arsenic for both treated and raw waters.

SMCL Parameters

Secondary MCL parameters for drinking water are directed at non-health related issues such as taste and odor. PWSs do not collect compliance data for most parameters with SMCLs. Table M-4A utilized only compliance data and, consequently, it includes little data for treated water for parameters with SMCLs. The raw water data collected through new well samples, however, provides information on the distribution of these parameters.

Multiple PWSs display elevated **chloride**. The largest numbers of PWSs with elevated chloride are associated with the sandstone aquifers followed by sand and gravel aquifers and carbonate aquifers. This may be related to limited natural oil and gas deposits occurring within aquifers, contamination of local aquifers from surface handling of oil and gas production brines, local salt storage facilities overlying sensitive aquifers, road salt application, or septic systems. Transportation routes are concentrated in the broad, flat buried valleys and consequently, large salt piles are stored on these broad valleys, which are sensitive aquifers. Activities to address chloride contamination are discussed in the Major Sources of Ground Water Contamination section.

Iron and manganese, have similar oxidation-reduction solubility controls as arsenic and widespread distribution and thus exhibit elevated numbers of PWSs in the watch list and impaired category of Table M-4A for raw water. Table M-4A utilized only compliance data so little data for treated water is included for iron and manganese. The raw water concentration for Fe and Mn are controlled by the increased solubility of iron and manganese in reduced waters. The deeper wells generally exhibit more reduced conditions (e.g., reduced interaction with the atmosphere) and, consequently, elevated iron and manganese. Iron is a common element and is present in all three major aquifers. For manganese, the carbonate aquifer is least likely to exhibit concentrations above the SMCL. Many PWSs remove iron and manganese, so the percentage of PWSs that exhibit impairments in treated water is significantly lower than in raw water.

Sulfate also has an SMCL and only raw water data exists for identifying water quality impacts. A significant number of PWSs exhibit elevated sulfate in the both the watch and impaired categories as illustrated in Figure M-5. Although these sites are distributed in all major aquifers, the carbonate aquifers in NW Ohio exhibit the highest percentage of PWSs on the watch list and in the impaired category (44 percent of carbonate vs. 10-12 percent for sandstone and sand and gravel) due to the presence of evaporates (Gypsum, $CaSO_4 \cdot 2H_2O$) in the Salina Formation in northwest Ohio.

Figure M-5. Distribution of PWSs in impaired category and on the watch list for sulfate in raw water.

Fluoride has no PWSs in the impaired category for raw or treated water, however, a number of PWSs exhibit watch list concentrations in treated and raw water. Fluoride is unusual in that it has a primary and secondary MCL and the SMCL is 50 percent of the MCl. Thus, all of the systems on the watch list for the MCL exceed the SMCL. The distribution of the fluoride watch list systems for both raw and treated water are plotted in Figure M-6. The Fluoride Technical Report (2012) describes how fluorite, which was deposited as a secondary mineral in fractures in the carbonate aquifers, controls the distribution of elevated fluoride.

Figure M-6. Distribution of PWSs on fluoride MCL watch list for treated and raw water.

For **nitrate and nitrite**, maximum values were used rather than average values to reflect the acute nature of the nitrogen MCLs. As a parameter that is stable in oxidized environments, nitrate is more likely to be present in shallower wells. Approximately 2.9 percent (149 of 5074) of PWSs in Table M-4A (treated water) have maximum nitrate greater than 50 percent of the MCL. Approximately 50 percent of these PWSs are located in sand and gravel aquifer settings. A PWS that exceeds 50 percent of the nitrate MCL is required to sample for nitrate on a quarterly basis. Thus, over the last decade, at least 150 PWSs have been required to increase nitrate sampling to at least quarterly. For nitrate in treated water and raw water, 24 and 22 PWSs fall into the impaired category, respectively. PWSs with maximum results greater than the MCL do not necessarily indicate an MCL exceedance, which is an annual average.

PWSs with elevated nitrate tend to be associated with more sensitive aquifers such as buried valleys and areas of thin glacial drift over bedrock. Stable nitrate (where decadal averages are relatively high) tend to be found in systems that combine a shallow aquifer with rapid pathways between surface and ground water and stable oxic or sub-oxic ground water. The number of PWSs with maximum nitrates in treated water in the watch list or impaired categories has decreased since 2010 based on the 2010 (243 PWSs), 2012 (227 PWSs), 2014 (181 PWSs) and 2016 (149 PWSs) Integrated Reports. This is encouraging, but probably reflects improved treatment or use of alternative sources, rather than reduction in nitrate loading. Figure M-7 illustrates the distribution of the PWSs with maximum nitrate above the MCL for both raw and treated water. The PWSs in Figure M-7 tend to cluster along buried valley aquifers, but some occur in bedrock aquifers below thin till or overburden.

Figure M-7. Distribution of PWSs with maximum nitrate in treated and raw water greater than the MCL.

Organic Parameters

For the organic parameters, the mean concentration of treated water samples for six organic parameters has placed PWSs in the impaired category: **1,2-dichloroethane**, **1,1-dichlorethylene**, **1, 2-dichloropropane**, **dichloromethane**, **tetrachloroethylene** and **vinyl chloride**. Two of these parameters are common solvents and the third is a compound used to make plastic. Dichloromethane (methylene chloride) is a known lab contaminant, but it is also possible that it can leach to ground water before it volatilizes, so it is included in Table M-4A. In addition to the PWSs identified above, there are about 15 PWSs that are not using a production well or are using air strippers to remove VOC contamination from ground water prior to use. The raw water data may include some of these systems, but if these ground water-based PWSs were not removing VOC contaminants, additional constituents would be identified as

impaired.

Pesticides and Synthetic Organics

One pesticide and synthetic constituent is identified as impaired, **di(2-ethylhexyl)phthalate.** These data confirm that although we see impact from pesticides and other organic compounds migrating to major aquifers, the protection that the till cover and tile drainage provide to protect Ohio ground water is significant.

Radiological Parameters

For treated water, several PWSs are included on the watch list and the impaired category for **gross alpha** and **radium 228**. The limited number of PWSs in the watch list and impaired category is consistent with the Ohio's geologic setting having few natural sources of radionuclides. The exceptions are uranium associated with reduced geologic settings like glacial tills, the Ohio Shale and coal deposits, but these settings are generally not utilized as aquifers. Gross beta compliance monitoring focuses on anthropogenic sources of radiation. The distribution of radionuclides is discussed in the DDAGW technical report *Radionuclides in Ohio's Ground Water* (July 2015).

Ambient Ground Water Quality Monitoring Data

Mean values were calculated from the AGWQMP data (raw water) for each well over the past ten years (2005 through 2014) to determine the number of wells in the watch list and impaired categories for each constituent. These numbers are listed in Table M-4B by parameter and major aquifer. The number of wells used in the determinations is also presented to provide the relative number of wells that exhibit ground water quality with elevated concentrations of MCL parameters. A limited number of AGWMP wells are listed in the watch list and impaired category, as was the case for the PWS compliance data. The results for groups of parameters are discussed below.

Inorganic Parameters

The AGWQMP does not collect data for antimony (except for one sandstone well), asbestos, beryllium, cyanide, mercury, nitrite, silver and thallium, so no comparison can be made to the PWS data. These parameters are not analyzed due to their historically low concentrations in Ohio ground water. No well waters are impaired (have decadal averages that exceed the MCL or SMCL) for barium, cadmium, chromium, fluoride, selenium and zinc. Several wells exceed 50 percent of the fluoride MCL. These wells produce water from the carbonate aquifer, as was seen with PWSs in Table M-4A and Figure M-6. A few well means are greater than 50 percent of the barium MCL, but as stated above, no impairments were identified. Averages for chloride exceed the SMCL in a few cases. Ten wells have chloride above 50 percent of the SMCL and an additional three wells exceed the SMCL. The source of contamination is likely associated with improper storage of salt for road deicing, oil and gas drilling brine disposal, brines in bedrock aquifers with a history of oil production, or road deicing.

Blank spaces indicate no wells exceed the standards (zeros left out to emphasize impacted wells). "nda" indicates no data available

- * Numbers for nitrate and nitrite are based on maximum values to reflect the acute nature of contaminant.
- ** MCL is for combined Radium 226 and Radium 228

For **nitrate**, well maximums were used rather than averages to reflect the acute nature of the nitrate MCL. This approach makes it difficult to compare the nitrate numbers to numbers for other parameters in Table M-4B. Nitrate is stable in oxidized environments and, thus, is more likely to be detected in shallower wells that have rapid exchange pathways with the atmosphere and surface water. In the AGWQMP, the sand and gravel wells are generally the shallowest and consequently, would be expected to exhibit the largest number of wells with elevated nitrate concentrations. This is the case with about seven percent of the sand and gravel wells exceeding 50 percent of the MCL. Four percent of the carbonate wells exceed 50 percent of the MCL, probably associated with sensitive karst settings and only two and-one-half percent of the sandstone wells are on the watch list for (maximum) nitrate. The AGWQMP tends to collect samples from higher production wells located deeper in aquifers; consequently, it is not the best program to evaluate ground water quality in shallow (e.g., 25 to 50 feet), sensitive aquifer settings.

Arsenic, iron, manganese, total dissolved solids (TDS) and sulfate mean concentrations result in significant numbers of wells on the watch list and in the impaired category. These are the same parameters identified in the PWS compliance data, with the addition of TDS. TDS is not required or collected for PWSs compliance data. Except for arsenic, all of these parameters have SMCLs and treatment is generally not required. Many PWSs remove iron, with the additional benefit of manganese and arsenic removal, since arsenic and iron solubility are controlled by similar redox controls. Sulfate in the AGWQMP is elevated in carbonate aquifers due primarily to the presence of evaporates in the Salina Formation, in the upper portion of the Silurian carbonate aquifer. For the carbonate aquifers, 58 percent of the ambient sites exceed 50 percent of the SMCL for sulfate, which is significantly higher than the percentage of sandstone and sand and gravel aquifers (10 percent and 4.5 percent respectively). The elevated TDS in raw water results from the relative solubility of aquifer material and the residence time for ground water in all of Ohio's major aquifers. The carbonate aquifers generally have higher mean TDS, but all three main aquifers exhibit high percentages of ambient sites with TDS exceeding 50 percent of the SMCL.

Organic Parameters - Detection of organic parameters at and above watch list concentrations is not common in the AGWQMP. Detected organic parameters above the MCL include dichloromethane, trichloroethylene and vinyl chloride. These organic solvents were detected in PWSs raw water samples as listed in Table M-4A.

Pesticides – No pesticides were detected in the AGWQMP wells above 50 percent of the MCL. The AGWQMP does not analyze for pesticides on a regular basis, as reflected in the low number of wells listed for pesticides, due to the lack of pesticide detections during several sampling rounds in the late 1990s. This sampling and consultations with the Ohio Department of Agriculture regarding its pesticide

sampling results, suggests that further pesticide data collection is not cost-effective for the AGWQMP. Review of available data supports the conclusion that the glacial till provides protection for Ohio's ground waters based on low detections rates and low concentrations detected. Nevertheless, local sensitivity and improper use of pesticides can lead to pesticide impacts. The historic data points to the greatest impacts occurring at the mixing sites or areas of spills.

Radiological Parameters – Radiological parameters are not included in the AGWQMP sampling.

Comparison of PWS and AGWQMP Data

Overall, we see similar trends in the PWS compliance and the AGWQMP data. This confirms that the AGWQMP data are appropriate for identifying long-term trends in the ground water quality of the major aquifers utilized by the PWSs. Thus, the AGWQMP goal of monitoring and characterizing the ground water quality utilized by PWSs in Ohio is validated by these empirical data.

It is interesting that the ground water quality differences documented between the major aquifers in AGWQMP data based on major components are not obvious in Tables M-4A and M-4B. The major elements or components (Ca, Mg, Cl, Na, K, sulfate and alkalinity) are generally the parameters utilized to identify water types. However, Ca, Mg, K and alkalinity do not have MCLs or SMCLs, so MCL and SMCL comparisons are limited in their capacity to delineate geochemical differences among waters from different aquifers. Chloride and sulfate do have SMCLs and exhibit significant differences between the major aquifers as noted above in Tables M-4A and M-4B. Treatment, such as softening, of PWS-distributed water can mask differences in water quality between major aquifers.

The most recognizable geochemical differences between the major aquifers in Ohio relate to the concentrations of calcium, magnesium, bicarbonate and strontium. These differences relate to the higher solubility of carbonate rocks and the long water-rock reaction time of ground water. The carbonate waters are characterized by elevated calcium, manganese, bicarbonate and strontium compared to water in sandstone and sand and gravel aquifers. The higher percentages of PWSs that exhibit watch list and impaired category results for TDS and sulfate in the carbonate aquifers reflects the dissolution of gypsum within the carbonate stratigraphy. Summary data from the AGWQMP provides a description of Ohio's major aquifers and their water quality and are presented in the technical report, *Major Aquifers in Ohio and Associated Water Quality (2015)*, which is included as Appendix A to this chapter.

M7. Ground Water-Surface Water Interaction

DDAGW special studies generally focus on water quality impacts in ground water associated with recharge in sensitive geologic settings. Thus, special studies provide information on the ground water-surface water (GW-SW) interaction related to surface water recharge and contaminants transported with recharge. Two technical reports completed in 2014-2015 and ongoing projects document elements of the GW-SW interaction. Brief summaries of these studies are provided below.

The technical report *Reduction-Oxidation* (*Redox*) *Control in Ohio's Ground Water Quality* (2014) describes the control redox conditions have on several common water quality parameters, such as nitrate, manganese, iron and sulfate. This document describes how microbes mediate electron transfer reactions and promotes understanding of redox as it relates to water quality. This document provides tools for anyone reviewing ground water quality data to identify the relative position of the aquifer in the redox range from oxic to methanogenic, if selected parameters are analyzed. The oxic portion occurs at the surface of the water table and is controlled by oxygen exchange with the atmosphere and/or the

migration of oxidized surface water recharge to the aquifer. The Hydrogeologic Sensitivity Assessment (HSA) procedure developed for the Ground Water Rule uses redox conditions as an indicator of the time of travel for surface recharge to reach the production aquifer. If E. coli is found in aquifers with reducing conditions, it is interpreted to indicate that rapid recharge pathways are present. Since E.coli is not well adapted to the vadose and aquifer environments, it is unlikely to survive long enough to make the trip from the surface unless hydrogeologic barriers are short circuited, allowing rapid migration of surface recharge to the production aquifer. Thus, the HSA utilizes indications of rapid recharge to evaluate sensitivity of local aquifers to pathogen migration.

The draft *Strontium in Ohio's Ground Water* technical report documented the elevated strontium associated with the carbonate aquifers as described in section M-3 and illustrated in Figure M-3. The Unregulated Contaminant Monitoring Rule 3 data show that multiple PWSs using surface water exhibit elevated strontium. This is attributed to the influence of baseflow during low flow conditions and documents the direct link between ground water and surface water. Figure M-8 illustrates the relationship between strontium and discharge in the Sandusky River at the Fremont gauging station. The influence of elevated strontium in ground water can cause problems for facilities requesting discharge permits. These examples document why we need to maintain the efforts to integrate ground water and surface water.

Figure M-8. Strontium in surface water in the Sandusky River at Fremont

The Division of Drinking and Ground Waters continues to sample three ODNR observation wells selected for ground water quality monitoring in conjunction with the water level data collected by ODNR. The purpose is to evaluate correlations between static water level and water quality at a high sampling density. Samples have been collected monthly since June 2012 and, starting in May 2014, the sampling was shifted to quarterly. Starting in July 2014, samples to characterize the microbial community structure, function and activity and to identify microbial signatures of metal release in ground water, were collected by Dr. M. Wilkins and graduate students at The Ohio State University. Preliminary results will be evaluated in 2016.

M8. Conclusions and Future Directions for Ground Water Protection

Ohio is fortunate that ground water is plentiful across the state. With the exceptions of a few areas that exhibit effects of over-pumping, decreasing static water levels have not been documented across extensive areas. Some new, high-yielding agricultural wells are being installed, but the duration of pumping is generally limited, so annual recharge appears to replenish the aquifer. Although the quantity of ground water appears stable, the documentation of water quality impacts in this document illustrate that continued protection of ground water resources is necessary. Ground water contamination can eliminate the potential use of water resources, just like diminished quantities. If other water sources are not available, additional treatment will increase the cost of providing a needed resource.

As documented in the previous sections, numerous sites exhibit ground water contamination from anthropogenic and natural point and nonpoint sources. The alternative to combat natural sources of contamination that cause impairment of drinking water is to develop and install treatment that removes the contamination or to locate another water source. The options for managing anthropogenic sources are more numerous, with the most constructive focusing on prevention of releases that migrate to ground water. Instituting best management practices (especially for the use of fertilizers and salt storage), implementing appropriate siting criteria for new waste storage and disposal sites and improving design for material storage and waste disposal facilities are proactive approaches to prevent releases to ground water. These kinds of proactive practices are critical to the sustainability of Ohio's high quality ground water resources.

The ongoing implementation of the Source Water Protection Program (SWAP) for Ohio's public water systems helps raise awareness of ground water quality issues and promotes source water protection planning. The SWAP potential contaminant source inventory data was instrumental in identifying and ranking major sources of contamination near public water systems, as listed in Table M-3 in the 2012, 2014 and 2016 Integrated Reports. SWAP staff has also had key roles in the development of several guidance documents to help protect ground water in association with the SCCGW.

Generally, awareness and concern about ground water resources is increasing. State agencies are working together to develop appropriate guidance or guidelines for activities that may threaten ground water. This is documented by the development of the *Recommendations for Geothermal Heating and Cooling Systems* (February 2012) and *Recommendations for Salt Storage* (February 2013). The most recent guidance is the updated *Regulations and Technical Guidance for Sealing Unused Water Wells and Boreholes*, finalized in March 2015. ODNR, in conjunction with several other agencies, has revised and developed fact sheets and best management practices to provide information on water resource issues associated with shale gas development. These documents are available on the ODNR Division of Oil & Gas Resources Web Page in the Shale activity section: http://oilandgas.ohiodnr.gov/shale#SHALE

To help provide well owners information on water quality, Ohio EPA worked with ODH and OSU Extension on the development of a new Web-based water quality interpretation tool for private well owners. In the "Know Your Well" tool, water sample results from a lab sheet are entered into the tool and with one click, well owners are provided with the standard for the parameter of interest, the natural range in ground water in Ohio for comparison, recommendations on actions, health effects and treatment options if applicable. The tool is part of this website hosted at OSU Extension at:

http://ohiowatersheds.osu.edu/know-your-well-water

In 2013, a new relational database, GWQCP, was completed for DDAGW. This database houses water

quality data for non-compliance projects in DDAGW. The completion of reports for pulling data from the database, user's guides and updates of the Operating Procedures Document were completed in 2014, with final review in 2015. Thus, the database and documentation are now in place. Other activities completed over the past two years include:

- A discussion of future directions for the GW Characterization Program
- Extended sampling interval for geochemically stable wells
- Addition of new sandstone and carbonate wells

The Ambient Ground Water Quality Monitoring Program continues to collect high quality raw water data. The long-term nature of these data, dating back to the 1960's for some wells, allows evaluation of long-term ground water time series, which are extremely valuable for appraising the sustainability of the resource. These data from active PWS production wells place a priority on collecting water quality data to evaluate and characterize the ground water resource that is utilized. The GWQCP staff works to use ground water quality data to support and direct activities of the DDAGW as well as to provide these data to the public and other programs.

With the new database and documentation in place, the current focus of the Ground Water Characterization Program is to analyze the data and to increase the availability of these data to the public. The main approach to accomplish this will be to continue to generate the technical reports and fact sheets, with reports on iron & manganese, nitrate, chloride and barium to be completed next year. This effort will continue to document the value of the AGWQMP data. Other goals for the AGWQMP are to work to include the wells in the National Ground Water Monitoring Network, include methane in the parameter list and continue to anticipate future water quality needs.

Ohio's ground water resources are relatively well-protected from surface contamination due to the layer of low-permeability glacial till that overlies approximately two-thirds of the state. Long-term efforts to protect ground water quality need to focus on aquifers subject to rapid recharge from the surface, such as shallow fractured bedrock, karst bedrock and shallow sand and gravel units.

Ground Water Section Appendix

Appendix A – Major Aquifers in Ohio and Associated Water Quality

This technical report provides a description of Ohio's major aquifers and their distribution. The water quality of these aquifers is described by providing mean, median, minimum and maximum values for all AGWQMP (raw water) data from active wells by aquifer type. Well means are also presented as boxplots for individual constituents, in the report appendix. This provides a visual representation of the variability of parameters within and between the major aquifer types.

Division of Drinking and Ground Waters Technical Series on Ground Water Quality October 2015

The Technical Series on Ground Water Quality:

This series of reports provides information to the professional/technical community about ground water quality in Ohio's aquifers. These reports use data from:

- the ambient ground water quality monitoring program; and
- the public water system compliance programs.

These data, representative of raw water, are used to characterize the distribution of selected parameters in ground water across Ohio. The goal is to provide water quality information from the major aquifers, exhibit areas with elevated concentrations, and identify geologic and geochemical controls. This information is useful for assessing local ground water quality, water resource planning, and evaluating areas where specific water treatment may be necessary.

A series of parallel fact sheets, targeted for the general public, provide basic information on the distribution of the selected parameters in ground water. The information in the fact sheets is presented in a less technical format, addresses health effects, outlines treatment options and provides links to additional information.

Disclaimer

The Ohio EPA, Division of Drinking and Ground Waters (DDAGW) is providing information in this technical series as a public service. While Ohio EPA believes this information to be reliable and accurate, some data may be subject to human, mechanical or analytical error. Therefore, Ohio EPA does not warrant or guarantee the accuracy of these data. Because of the variability inherent in ground water data, caution must be taken in extrapolating point-data beyond the collection site. The accuracy, completeness, suitability and conclusions drawn from the information presented here are the sole responsibility of the user.

Technical Series Major Aquifers in Ohio and Associated Water Quality

Abstract

The major aquifers are described and ground water quality data is presented that characterizes them. The data presented provides ranges of constituent concentrations typical of the major aquifers across Ohio. These data are representative of source water utilized by public water systems (raw or untreated water). These data are not pristine, since a number of the AGWQMP wells are impacted by elevated chloride, nitrate and organic parameters sourced from surface activities. The inherent variability in ground water means care must be taken when extrapolating point data beyond the collection site. However, the information compiled in this report is the best summary available for the general water quality of Ohio's major aquifers, and is presented to help evaluate water quality in local aquifers.

Introduction

The purpose of this report is to:

- Summarize information on Ohio's major aquifers;
- Discuss factors that influence the water quality within aquifer types; and
- Present water quality data representative of the major aquifers.

This information is intended to help evaluate local water quality by providing ranges of parameter concentrations typical of Ohio's major aquifers for comparison. The water quality data presented has been collected by Ohio EPA's Ambient Ground Water Quality Monitoring Program (AGWQMP) and is representative of raw or untreated water.

Ohio's Major Aquifers

Ohio has abundant surface and ground water resources. Average precipitation ranges between 30 to 44 inches a year (increasing from northwest to southeast), which drives healthy stream flows. Infiltration of a small portion of this precipitation (3-16 inches) recharges the aguifers and keeps the streams flowing.

Ohio's aquifers can be divided into three major types as illustrated in Figure 1 (modified from ODNR Statewide Aquifer Maps, 2000). The sand and gravel buried valley aquifers (in blue) are distributed as thin bands through the state. The valleys filled by these sands and gravels are cut into sandstone and shale in the eastern half of the state (in tans) and into carbonate aquifers (in greens) in the western half. The sandstone and carbonate aquifers generally provide sufficient production for water wells except where dominated by shale, as in southwest and southeast Ohio.

Sand and Gravel Aquifers

The unconsolidated sand and gravel units, typically associated with buried valley aquifers, are Ohio's most productive water-bearing formations. These valleys were cut into the bedrock by pre-glacial and glacial streams and were subsequently back-filled with deposits of sand, gravel and other glacial drift by glacial and alluvial processes as the glaciers advanced and receded. Buried valley aquifers are found beneath and adjacent to the Ohio River, its major tributaries, and other pre-glacial stream channels such as the Teays River.

Figure 1. Aquifer Types in Ohio modified from ODNR Glacial and Bedrock Aquifer Maps.

In addition to the buried valley aquifers, lenses of sand and sand and gravel within glacial tills may be productive, although generally providing lower yields than the buried valley aquifers. Outwash/kame and beach ridge deposits are also important sand and gravel aquifers in local areas. Several other types of extensive sand and gravel aquifers are included in Figure 1. In the northwest corner of the state, the triangular area of sand and gravel units bordering Michigan and Indiana includes sheets of outwash or sand and gravel that occur between sheets of glacial till. The large patches of sand and gravel just east of the triangular outwash deposits are reworked delta deposits of the Oak Opening Sands. Present day stream processes deposit alluvial sand and gravel deposits that also serve as aquifers if the alluvial deposits are thick enough.

Water production from the coarser-grained and thicker sand and gravel deposits ranges up to 500 to 1,000 gallons per minute (gpm). However, lower yields from sand and gravel aquifers are more common. The production depends on the type, distribution, permeability, and thickness of aquifer materials and well construction parameters, such as borehole diameter, screen length, and development. Yields of these unconsolidated aquifers are illustrated on the ODNR web site at:

http://water.ohiodnr.gov/maps/statewide-aguifer-maps

in the Example Maps created from SAMP Data section.

Sandstone Aquifers

In eastern Ohio, Mississippian and Pennsylvanian sandstones and conglomerates are the dominant bedrock aquifers (Figure 1). Sandstone and conglomerate units of variable thickness and areal extent are interbedded with numerous layers of siltstone and shale with minor amounts of limestone, clay, and coal. The sandstones generally dip a few degrees to the southeast, toward the Appalachian Basin. Some of the thicker sandstones and conglomerates can yield 50 to 100 gpm, but 25 gpm is good for these aquifers. The more productive stratigraphic units include:

- Pennsylvanian Sharon through Massillon Formations, and the Homewood Sandstone within the Pottsville and Allegheny Groups These sandstones, including some conglomerates, were deposited on a stable coastal plain with rising sea level. These aquifers are most commonly used in the northern areas of eastern Ohio. To the southeast, farther into the Appalachian Basin, the water is generally too saline for drinking.
- Mississippian Berea Sandstone, Cuyahoga Group, Logan and Blackhand Formations These
 siltstones and sandstones with minor conglomerate were sorted and deposited in deltaic
 complexes from material eroded from the Acadian Mountains (Late Devonian uplift) to the east.
 These units also extend to the southeast, farther into the Appalachian Basin, but as with the
 Pennsylvanian units, the water becomes too saline for drinking.

In southeastern Ohio, Upper Pennsylvanian and Permian stratigraphic sections include low-yielding aquifers. The bedrock consists of varied sequences of thin-bedded shales, limestones, sandstones, clays, and coals of the Pennsylvania Conemaugh and Monongahela Groups and the Permian Dunkard Group. Yields below five gpm are common in these areas as illustrated in Figure 2 (from the ODNR web page at:

http://water.ohiodnr.gov/maps/statewideaquifer-maps in the Example Maps Created from SAMP Data section.

Carbonate Aquifers

Carbonate bedrock is the dominant aquifer in western Ohio (Figure 1). Silurian and Middle Devonian limestone and dolomite reach a total thickness of 300 to 600 feet, and are capable of yielding from 100 to over 500 gpm. Higher production units are associated with fractures and dissolution features that increase the permeability. The high production aquifers, in order of deposition, are fractured or karst Silurian sub-Lockport/ Lockport Dolomite and equivalent units, the Salina Group, consisting of the Tymochtee and Greenfield Dolomites, and

Figure 2. Typical yields for bedrock aquifers.

the Undifferentiated Salina Dolomite and equivalent evaporites. The Devonian Columbus and Delaware Limestones, exposed along the eastern edge of the Silurian Dolomites, and equivalent Devonian units in the northwest corner of Ohio (Detroit River Group, Dundee Limestone, Silica Formation, and Ten Mile Creek Dolomite) are productive carbonate aquifers. These carbonates were generally deposited in warm, shallow seas with limited input of sediment from continental sources. Where the Devonian limestone is overlain by 100 feet or more of Devonian shale, the water quality is poor and generally cannot be considered a drinking water source.

Southwestern Ohio is underlain by inter-bedded lower Ordovician carbonates and shales. These units are dominated by shale (Figure 1). As a result, well yields are generally less than 10 gpm, and in many areas, are less than one gpm (Figure 2). Consequently, in southwestern Ohio (as in southeastern Ohio), public water systems depend on the buried valley aquifers as the main ground water source. These low yielding aquifers are only practical for low volume use. Ohio EPA has little water quality data from shale-dominated wells, and consequently, they are not discussed further in this report. Another area with low yields is the region of Devonian shale that overlies the Columbus and Delaware Limestone aquifers. The narrow north-south trending area of Devonian shale in central Ohio is clearly illustrated in Figure 2 as the area of low yields (0-5 GPM) that separates the carbonate aquifers in the west from the sandstone aquifers to the east. Where the north trend of the shales meets Lake Erie, the shale curves eastward along the Lake Erie shoreline as illustrated in Figure 2 by the band of low yields there. In addition, to the low yield, hydrogen sulfide is frequently present, which causes water quality problems.

Ground Water Quality by Aquifer Type

General Considerations

The overall ground water quality in Ohio is described here using the Ambient Ground Water Quality Monitoring Program (AGWQMP) database, which consists of approximately 6,000 inorganic and 2,600 organic water quality samples distributed across 282 active wells. Figure 1 illustrates the distribution and aquifer type of AGWQMP wells. As described above, the major aquifers include unconsolidated sand and gravel units deposited on sandstone bedrock in eastern Ohio and carbonate bedrock in western Ohio. The majority of the wells used in this characterization are public water supply production wells, usually developed within higher yielding zones with good water quality. This effort supports the goals of the AGWQMP - to collect, analyze, and describe the source (ambient) ground water quality used by public water systems across the state.

AGWQMP data are presented by major aquifer type. Water-rock interaction along flow paths imparts distinct geochemical signatures which are reflected in the ground water quality. Several factors contribute to the chemical makeup of ground water; the most significant are the composition of the recharge (percolation) water, the soil and vadose zone composition, the composition of the aquifer solids, and the residence time of the ground water. These factors vary widely across the three main aquifers types in Ohio, but some broad observations are possible. In general, the initial composition of percolation water across the state is similar. Long-term average precipitation for Ohio is 38 inches per year, while ground water recharge rate estimates range from 3 inches to 16 inches per year, with a median of 6 inches per year (Dumochelle and Schiefer, 2002). Composition and solubility of soil and vadose materials vary, however, leading to recharge waters with variable initial compositions. The thick glacial tills (clayey soils) found across much of north, central, and west Ohio affect the initial percolation water quality differently than the weathered colluvium with variable amounts of loess in southeast Ohio. The permeability of the heavy glacial soils tends to increase the residence time; however, agriculture tile drains in many of these glacial soils can short circuit flow paths to surface water and thus, reduce the

volume of recharge reaching local aquifers.

Increased residence time in an aquifer typically leads to higher salinity and greater mineralization of the water, depending on the solubility of the aquifer minerals present. Sand and gravel aquifers, for example, commonly have short residence times, leading to lower salinity. These younger waters are generally shallower, and are more likely to be affected by contamination from land use activities. Older, deeper waters, such as found in the carbonate aquifers of northwestern Ohio, may follow much longer flow paths, allowing the water ample time to establish a geochemical equilibrium with the rock system. Figure 3 is a box plot indicating the distribution of well depths by aquifer type for the AGWQMP wells. The median depth in the carbonate aquifers (~225 feet) is slightly greater than the median depth in the sandstone aquifers (~220 feet). The median depth for the sand and gravel aquifers (~90 feet) is less than one-half the depth of the carbonate or sandstone aquifers, suggesting shorter residence times for sand and gravel aquifers compared to bedrock aquifers.

Figure 3. Box plot of active AGWQMP well depths by aguifer type.

Inorganic Parameter Mean Values

Ambient ground water quality data presented in Table 1 (starting on page 10) summarize the geochemistry by major aquifer type for all active AGWQMP wells. This table provides the arithmetic mean, median, minimum value, maximum value, standard deviation, total number of samples, number of samples below the reporting limit, and the percent non-detect for all individual inorganic and field

parameter results in each aquifer type as of July 2015. Brief descriptions of several of these parameters are provided to aid in understanding the data. For instance, the reporting limit was used for the non-detect values in calculating means and standard deviation. The "non-detect" column records the percent of analyses with results below the reporting limit (rounded to the nearest percent). The presence of a less than sign (<) in the minimum value field (column 5) indicates the minimum value is the reporting limit. The minimum value may not coincide with the current reporting limit due to changes in analytical methods. AGWQMP sampling started in 1973, and changes in analytical methods resulted in multiple reporting limits for some constituents. The estimates of the number and percentages of non-detect data (columns 8 and 9) may also be influenced by changes in the reporting limits.

Table 1 summarizes the accumulation of over 164,000 raw, inorganic ground-water data results gathered at 282 active and standby wells across Ohio over 40 years of sampling. Consistent sampling protocol, analytical procedures, and long site histories lend a unique significance to these data. Table 1 is the best summary available for the general water quality of Ohio's major aquifers, which provides the source water for Ohio's public drinking water systems using ground water. Note, however, that some wells in the AGWQMP network have been influenced by anthropogenic sources, such as nitrates or VOCs. Thus, the water quality presented is not pristine, but rather is typical of the ground water quality of aquifers utilized for source water by the public water systems.

The data listed in Table 1 is organized into four categories:

- Field Parameters measured in the field, such as pH and water temperature;
- Major Constituents such as calcium or sulfate; concentrations in the range of mg/L;
- Trace Constituents such as arsenic or cadmium; concentrations in range of μg/L; and
- Nutrients components required by organic systems for growth; concentrations in mg/L.

The statistical parameters in Table 1 were generated using individual sample result values. This is complemented by a graphical summary using box and whisker plot diagrams based on means for each well in Appendix A. In Appendix A box plots, the inorganic results are plotted on the Y-axis, while the X-axis represent the three major aquifer groupings (sand and gravel, sandstone, and carbonate).

Use of Primary and Secondary MCLs

Maximum Contaminant Levels (MCLs) are health-based regulatory standards for permissible concentrations of constituents in drinking water delivered to the public. Secondary Maximum Contaminant Levels (SMCLs) are advisory limits applied to distribution water at public water systems for aesthetic water quality issues, such as taste and odor. Because AGWQMP data are obtained from raw (untreated) ground water, which is unregulated, any exceedance of an MCL or SMCL by an AGWQMP data point has no legal or regulatory consequence for the public water system. However, since MCLs and SMCLs are widely known, they represent a practical benchmark for discussion. MCLs and SMCLs are included in the first column of Table 1 and included on the boxplots in Appendix A for constituents that have established regulatory values.

Seven of the primary constituents for which health based MCLs exist are monitored in raw water through the AGWQMP. These are arsenic (10 μ g/L), barium (2 mg/L), cadmium (5 μ g/L), chromium (100 μ g/L), fluoride (4 mg/L), nitrate-nitrite as N (10 mg/L), and selenium (50 μ g/L). Additionally, copper and lead have action levels (not MCLs or SMCLs) of 1.3 mg/L and 0.015 mg/L respectively. As indicated by the

Ambient Ground Water Quality Table 1, no constituent exceeds a MCL based on averages by aquifer type. Arsenic exhibits the highest concentrations as a percentage of the MCL; nevertheless, mean concentrations for all three aquifer types are well below the arsenic MCL of 10 μ g/L (sand and gravel = 5.41 μ g/L, sandstone = 2.48 μ g/L, carbonate = 3.75 μ g/L). However, 30 active AGWQMP wells have raw water means that exceed the arsenic MCL of 10 μ g/L. If these wells are public water system wells, treatment would be required to bring arsenic concentrations below the MCL in the distributed water. Means for barium, cadmium, chromium, fluoride, nitrate-nitrite, and selenium are also below MCLs within all three aquifer systems. Individual well means indicate no MCL exceedances for barium, cadmium, chromium, fluoride, nitrate, and selenium, but three AGWQMP wells have barium means greater than 75 % of the MCL.

Nine constituents with established SMCLs are monitored by the AGWQMP. These are: aluminum (0.05 - 0.2 mg/L), chloride (250 mg/L), fluoride (2.0 mg/L), iron (0.3 mg/L), manganese (0.05 mg/L), pH (7-10.5 SU), sulfate (250 mg/L), total dissolved solids (TDS, 500 mg/L), and zinc (5 mg/L). The SMCL levels are exceeded by the aquifer means for several of these constituents as exhibited in Table 1, and by individual well means in Appendix 1.

Volatile Organic Compounds

Volatile organic compounds (VOCs) have been monitored in untreated water for the AGWQMP since the mid-1980s with a standard sampling frequency of 18 months. A reporting level of $0.5 \,\mu g/L$ (ppb) has been used consistently. Fortunately, the detection rate for VOCs is low, about $0.29 \,\mu c$ percent (506 detections from 172,077 results), but their presence usually indicates water quality impact from land use activities. AGWQMP sampling protocols may increase the sampling frequency if VOCs are detected; currently, 15 active AGWQMP wells are sampled for organics every six months to help evaluate potential for migration of VOC plumes into public water system wells. The higher VOC sampling frequency of wells with VOC detections increases the detection rates. In some cases, wells with VOC detections are abandoned by public water systems and are no longer available for sampling by the AGWQMP.

The five VOCs representative of point source origins that exhibit the highest rate of detections in active AGWQMP wells are listed in Table 2. The parameter name, the number of detections, the number of sites with detections, and the range of detections are listed below.

Table 2	. Most Frequen	tly Detected VOC	s in AGWQMP Wel	lls.
Parameter	Number of detections	Number of sites with detections	Range of results (µg/L)	Maximum Contaminant Level (MCL)
Trichlorloroethylene	68	8	0.5-44.2	5
cis-1,2- Dichloroethylene	59	11	0.5-4.92	70
loroethylene	53	6	0.5-28.5	5
Methyl tertiary butyl ether (MTBE)	33	4	0.5-6.73	none
1,1,1,Trichloroethane	11	2	0.5-1.39	5

Major Aquifers in Ohio and Associated Water Quality

Chlorinated solvents are the primary chemical group in Table 1. These include trichloroethylene (TCE), cis-1,2-dichloroethylene, tetrachloroethylene (PCE), and 1,1,1-trichloroethane (1,1,1-TCA). These solvents were developed over the last century as cheaper and more practical alternatives to petroleum solvents. PCE and TCE have been in industrial use over 60 years. PCE is widely used for dry cleaning. PCE and TCE can both undergo dechlorination (loss of a chlorine) leading to the daughter products 1,1-dichloroethylene, cis- and trans-1,2-dichloroethylene, which ultimately degrade into vinyl chloride. As a group, their concentrations in ground water are quite low, well below MCLs, but maximum values for TCE (14 results at one site) and PCE (2 of 53 results) are above MCL. The usage of multiple solvents or the degradation of one solvent to another can explain the occurrence of mixtures of these compounds found in some AGWQMP wells. MTBE, a gasoline additive (oxygenate), is also included in the top five list, but 29 of the 33 detections occur at one well and concentrations are generally decreasing in this well.

Most of the wells with VOC impact are associated with sensitive aquifers, which is not surprising considering the point source nature of most VOC sources. From a practical standpoint, most detections of VOCs should be considered water quality impacts, as there are few natural sources of these manmade chemicals. There are, of course, exceptions to this generalization, such as benzene from crude petroleum in aquifers known for oil production down dip or in associated stratigraphic units. The limited detection data and anthropogenic association of these organic compounds make them of little use in characterizing water quality, beyond the fact that their presence usually indicates water quality impacts from land use activities.

Trihalomethanes (THM) are the most frequently detected organic compounds in AGWQMP wells (119 detections at 33 sites), including chloroform, bromoform, dichlorobromomethane, and chlorodibromomethane. However, the source of these compounds is not always clear. The maximum value detected in active wells, 37 μ g/L, is well below the MCL of 80 μ g/L. Thrihalomethanes are a byproduct of disinfection using chlorine, and are not uncommon in public water system distribution water. Thus, if there is backflow from the distribution system to the AGWQMP sample location (leaking foot valve or poor sample tap location), or if the well has been disinfected recently, THMs may be present. A third possibility is that treated water from lawn watering or leaks in the distribution system or sewer lines is recharging local wells. The source of THMs in a well is not always clear, consequently, unlike the VOC detections, THM detections cannot always be attributed to land use impacts.

Summary

The major aquifers are described and water quality data is presented that characterizes them. The data presented provides ranges of constituent concentrations typical of the major aquifers across Ohio. These data are representative of source water utilized by public water systems (raw or untreated water). These data are not pristine, since a number of the AGWQMP wells are impacted by elevated chloride, nitrate and organic parameters sourced from surface activities. The inherent variability in ground water means care must be taken when extrapolating point data beyond the collection site. However, the information compiled in this report is the best summary available for the general water quality of Ohio's major aquifers, and is presented to help evaluate water quality in local aquifers.

Ambient Ground Water Quality Monitoring Program Inorganic Constituent Box and Whisker Plots

This document provides a concise geochemical summary, in box and whisker plot format, of the Ambient Ground Water Quality Monitoring Program (AGWMP) inorganic data set as of July 2015. The Box and Whisker plots from the Ambient Ground Water Quality Network database include results from 6000 raw (untreated), inorganic water samples collected over the past 40 years across more than 200 active wells. Active (AGWMP) wells are sampled every six, eighteen or thirty-six months. The primary objective of collecting statewide, raw ground water data from major aquifers is to characterize Ohio's ground water quality, which in turn is used to enhance water resource planning and to prioritize ground water protection. The AGWMP places a priority on collecting water quality data representative of aquifers used by public water systems. Analysis of water quality changes in space and time indicate that some of the AGWMP wells are influenced by land use activities. The wells are considered typical of the local ground water used as source water for public water systems.

In the following box plots, the water-quality results are first averaged by well, then grouped by the three major aquifer types in Ohio to display the numerical data distributions. Water quality results are plotted on the y-axes, while the x-axes represent the three major aquifer categories (carbonate, sandstone, and sand and gravel). These box plots allow the reader to visually compare data variability across major aquifer types. The analyzed constituents are presented in the following order: Field Parameters; Major Constituents; Trace Constituents; and Nutrients. The number of wells used to construct each group's box plot is indicated above the x-axis.

The y-axis is presented in linear or in log 10 scale, whichever enhances readability. Box plots that appear without "boxes" (common in Trace Constituents section) have too little data variability to generate separation of the 25th and 75th percentiles of the distribution (upper and lower box bounds). In these cases, the boxes appear collapsed to the most common data point, typically the Reporting Limit. Collapsed boxes generally occur when more than 75% of the data are below the reporting limit. In the case of chromium and nickel, high reporting limits in early data distort the representation of variability of these data. In both of these cases, the lower (current) reporting limit was used for all non-detect results to more accurately represent the distribution of chromium and nickel.

Construction and interpretation details for a generic box plot are found on the next page of this report.

Ground Water Quality Characterization Program

Box and Whisker Plots

Figure 1

Explanation of Box Plot construction.

Box and Whisker Plots are an efficient graphical method for displaying the distribution of a data set. The format allows easy comparison of one distribution to those of other groups of data. The elements of a typical boxplot are indicated in Figure 1. The "box" itself outlines the range of half the data (the 25th to 75th percentiles, called the Inter-Quartile Range, or IQR). The median of the data set (the 50th percentile) is indicated by a thick horizontal bar inside the box.

The whiskers are vertical lines extending from the top and bottom of the box, and indicate the range of data (which are not outliers) above and below the 75th and the 25th percentiles, respectively. The extent of the whiskers indicates the position of the last data point which does not exceed 1.5 times the IQR. Outliers exceed 1.5 times the IQR, and are identified by individual symbols above or below the whiskers.

A normally distributed data set is indicated if the median bar is located mid-way between the top and bottom of the box, i.e. if the median is equidistant between the 25^{th} and 75^{th} percentiles. A skewed data set would have the median bar either closer to the 25^{th} percentile (positively skewed) or to the 75^{th} percentile (negatively skewed).
